Draft baseline and monitoring methodology AM00XX

“Energy efficiency technologies and fuel switching in new buildings”

I. SOURCE, DEFINITIONS AND APPLICABILITY

Sources

This baseline and monitoring methodology is based on the following proposed new methodology:

This methodology also refers to the latest approved versions of the following tools:

- Tool to calculate emission factor for an electricity system.
- Tool to calculate project or leakage CO₂ emissions from fossil fuel combustion.
- Tool to calculate baseline, project and/or leakage emissions from electricity consumption.
- Tool to assess the validity of the original/current baseline and to update the baseline at the renewal of a crediting period.

For more information regarding the proposed new methodologies and the tools as well as their consideration by the Executive Board, please refer to <http://cdm.unfccc.int/goto/MPappmeth>.

Selected approach from paragraph 48 of the CDM modalities and procedures

“The average emissions of similar project activities undertaken in the previous five years, in similar social, economic, environmental and technological circumstances, and whose performance is among the top 20 per cent of their category”

Definitions

For the purpose of this methodology, the following definitions apply:

**Building unit.** Distinct space in a building allotted to a specific user, which can be either a tenant or owner. If a building has more than one tenant/owner,¹ a building unit is defined as a subordinate structure

¹ A tenant/owner can be either an individual, or a group of individuals sharing the same building unit.
of a building rented by one tenant or used by an owner.\textsuperscript{2} If a building is used by a single tenant/owner, the building unit is equal to the entire building.\textsuperscript{3}

**Gross floor area (GFA).** Area occupied by internal walls and partitions of a building unit. If a building unit contains common service areas in its physical boundary (meeting rooms, corridors, lift wells, plant and machinery, etc.), include GFA of the common service areas. Otherwise, GFA of the common service areas shall be excluded.

**Residential building unit.** A building unit used as one of the dwelling purposes listed in Annex 1.

**Commercial building unit.** A building unit used for one of the activities focusing on the exchange of goods and/or services for a profit listed in Annex 1.

**Institutional building unit.** A building unit used for one of the activities focusing on not-for-profit services in the public’s interest listed in Annex 1.

**Chilled water system.** Comprises all components needed to provide the cooling services by chilled water. It comprises one or several chillers plus ancillary equipment such as pumps for circulating chilled water and the condensing water and the fans to be used for circulating the cooling air in the condenser, associated piping, and the fans used to facilitate cooling at the cooling tower.

**Chilled water.** Water or water mixture that circulates through an evaporator unit, where it is cooled by a refrigerant as the latter evaporates. The chilled water in turn circulates to the applications that need to be cooled (e.g. space in buildings), where it exchanges heat, and is re-circulated back to the evaporation unit.

**Heating Degree days (HDD).**\textsuperscript{4} Heating degree days are a measure of how much (in degrees), and for how long (in days), the outside air temperature was below a certain level. They are commonly used in calculations relating to the energy consumption required to heat buildings.

**Cooling Degree Days (CDD).**\textsuperscript{5} Cooling degree days are a measure of how much (in degrees), and for how long (in days), the outside air temperature was above a certain level. They are commonly used in calculations relating to the energy consumption required to cool buildings.

**Hot water system.** A hot water system comprises all components needed to provide hot water. It consists of heat sources, water treatment apparatus, water heaters, pipelines to transport the hot water, and devices to regulate and control the water’s temperature.

**Municipality.** A political unit, such as a city, town, or village, incorporated for local self-government.

**Administrative boundary.** A limit or border of a geographic area under the jurisdiction of some governmental entity.

\textsuperscript{2} Residential building unit is an example. The term residential building unit refers to a single housing unit. Namely, a single family home is one residential building unit while a building with ten apartments has ten residential building units.

\textsuperscript{3} Schools are a typical example. As a school is normally occupied by an owner (e.g. municipality), the entire school building, not each classroom, is considered as a building unit in this methodology.

\textsuperscript{4} \texttt{<http://www.degreedays.net/>}.

\textsuperscript{5} \texttt{<http://www.degreedays.net/>}.
Applicability

This methodology applies to project activities that implement energy efficiency measures and/or fuel switching in new building units (residential, commercial, and/or institutional building units whose detailed categories are as defined in Annex 1). Examples of the measures include efficient appliances, efficient thermal envelope, efficient lighting systems, efficient heating, ventilation and air conditioning (HVAC) systems, passive solar design, optimal shading, building energy management systems (BEMS), and intelligent energy metering. Project proponents should clearly describe in the PDD the measures that are to be implemented under the project activity.

The methodology is applicable under the following conditions:

- Building units eligible for applying the methodology should belong to residential, commercial and institutional categories as defined in Annex 1;\(^8\)
- The sources of emissions eligible under the methodology are those including consumption of electricity, fossil fuel, and chilled water as well as leakage of refrigerant used in the building units;\(^9\)
- None of the project building units, that are used for the calculation of project emissions, and chilled/hot water systems, that supply water to the project building units, is fed electrical or thermal energy by biogas systems. This condition is to be verified both ex ante (BIOGPJ,ex-ante) and ex post (BIOGPJ,y);\(^10\)
- None of the project building units, that are used for the calculation of project emissions, and chilled/hot water systems, that supply water to the project building units, is fed electrical or thermal energy by biomass. This condition only concerns biomass-fired boilers, and excludes smaller appliances where only an insignificant amount of biomass is burned (e.g. barbecue pits). It is to be verified both ex ante (BIOMPJ,ex-ante) and ex post (BIOMPJ,y);\(^10\)
- None of the project building units, used for the calculation of project emissions, and chilled/hot water systems, supplying water to the project building units, is supplied electrical or thermal energy by cogeneration systems. This condition is to be verified both ex ante (COGENPJ,ex-ante) and ex post (COGENPJ,y);\(^11\)

\(^6\) HVAC (Heating, Ventilation and Air Conditioning) systems include filtration and, where required by the climate, humidification and dehumidification as well as heating and cooling.

\(^7\) BEMSs (Building Energy Management Systems) are control systems for individual buildings or groups of buildings that use computers and distributed microprocessors for monitoring, data storage, controlling and communication.

\(^8\) If the project participants require other categories than the ones listed in Annex 1, a request for revision of this methodology shall be made. Building units in other categories may be constructed as a part of the project activity, but shall be excluded from the application of the methodology.

\(^9\) Other energy consumption sources can be added by submitting a request for revision of this methodology.

\(^10\) The use of biogas/biomass could lead to methane emissions and leakage emissions, e.g. due to diversion of biomass from other uses to the project. These emission sources are not accounted for in the emission reductions calculation of the current version of this methodology. Thus, the use of biogas/biomass is excluded.

\(^11\) The current version of this methodology does not calculate emissions from the use of heat supplied by cogeneration systems. Thus, the use of cogeneration is excluded.
• The difference between HDD / CDD between municipalities in which the project building units are located should not be more that +/- 20%;

• None of the project building units used for the calculation of project emissions use chlorofluorocarbon (CFC) as a refrigerant. This condition is to be verified both \( \text{ex ante} \) (CFC\(_{PJ,\text{ex-ante}}\)) and \( \text{ex post} \) (CFC\(_{PJ,y}\));

• None of the project building units used for the calculation of project emissions claim CERs for emission reductions achieved by using efficient appliances being credited in other project activities registered as CDM projects. The overlapping use of the efficient appliances is to be verified both \( \text{ex ante} \) (OVERL\(_{PJ,\text{ex-ante}}\)) and \( \text{ex post} \) (OVERL\(_{PJ,y}\)). If there is no CDM project receiving CERs from the use of efficient appliances within the host country, this applicability condition is deemed satisfied. Otherwise, a discount factor shall be applied to the energy consumption of the project building units in order to avoid possible double-counting of emission reductions;

• All the project building units must comply with all applicable national energy standards (e.g. building codes) in the project boundary, if they both exist and are enforced. This condition is to be verified both \( \text{ex ante} \) (COMP\(_{PJ,\text{ex-ante}}\)) and \( \text{ex post} \) (COMP\(_{PJ,y}\));

• The renewable energy technologies that emit a material amount of GHG emissions (e.g. geothermal power plants, reservoir-type hydro power plants) are not allowed as a captive power source to project building units. However, geothermal plants are allowed to provide steam for chilled/hot water systems;

• The methodology is not applicable if only fuel switching measures are implemented in project building units.

In addition, the applicability conditions included in the tools referred to above apply.

II. BASELINE METHODOLOGY PROCEDURE

Project boundary

The spatial extent of the project boundary encompasses the area covering all the project and baseline building units. In addition, the spatial extent of the energy supply systems that supply energy to the project and baseline building units is included in the project boundary.

The spatial extent of an electricity system is as defined in the latest version of the “Tool to calculate emission factor for an electricity system”.

The spatial extent of a chilled water system(s) encompasses:

• All thermal sources directly serving the chilled/hot water system(s). In the case of geothermal heat extraction, the site of the geothermal heat extraction including geothermal wells, re-injection wells, pumps, geothermal water storage tanks, etc.

• All equipment including chillers, heating systems, pipes, sub-stations, pumps, cooling towers, meters, transformers and control equipment used for the supply of the energy service through chilled/hot water to users that are or will be connected to the chilled/hot water system(s).

• The electricity system to which the chilled/hot water system(s) is connected.
The greenhouse gases (GHGs) included in or excluded from the project boundary are shown in Table 1.

**Table 1: Emissions sources included in or excluded from the project boundary**

</table>

If a chilled/hot water system(s) is supplied heat by a geothermal plant(s), fugitive emissions of CH₄ and CO₂ from non-condensable gases contained in geothermal steam shall be accounted for.

All GHGs as defined by Annex A of Kyoto Protocol shall be considered, as per CDM Modalities and Procedures. However, if it is justified that the CDM project activity does not result in an increase of such emissions and the project emissions from the use of a refrigerant(s) is omitted from the calculation of the project emissions, the source shall be excluded.
Identification of the baseline scenario and demonstration of additionality

In this methodology a benchmark approach is applied to establish the baseline scenario. The calculation of the benchmark is outlined in the section “Baseline emissions” below. The baseline scenario is building units constructed and then occupied in the last five years in circumstances similar to the building units constructed and then occupied in the project activity, differentiated by building unit category.

Additionality of the project activity shall be demonstrated only for fuel switching measures employed in the project activity, if less carbon-intensive fuels used in the project building units were not commercially available within the project boundary in the last five years.

If the less carbon-intensive fuels were commercially available in the project boundary in the last five years, separate additionality demonstration of the fuel switching measures is not required because it is assumed that the top 20% benchmark will capture the autonomous fuel switching effect in the baseline. Based on the above, the following procedures shall be followed for the demonstration of additionality for fuel switching:

**Step 1:** Identify the less carbon-intensive fuel used in the project building units and check commercial availability of the fuel within the project boundary in the last five years. If the fuel has been commercially available in the last five years, it is not required to demonstrate additionality of the fuel switching measures. Otherwise, proceed to Step 2.

**Step 2:** Additionality of the fuel switching measures shall be demonstrated comparing the historical average retail price of the fuel used in the project building units since the fuel became commercially available within the project boundary (\(P_{PJ,Fuel}\)), with the fuel that was the most commonly used within the baseline building units for the same period (\(P_{BL,Fuel}\)). Retail prices per unit of energy (local currency unit/GJ) shall be used for the comparison. If the average retail price of the project fuel is higher than the one of the baseline fuel, the fuel switching measures are considered additional.

If the fuel switching measures are demonstrated to be additional or separate additionality demonstration of the fuel switching measures is not required, the project is deemed additional as long as the total emissions level from the building units constructed in the project activity is lower than the baseline emissions level calculated by the benchmark analysis during each year of the crediting period.

If the fuel switching measures are not demonstrated additional or the project activity does not claim CERs for emission reductions from the fuel switching measures, emission reductions from the fuel switching measures cannot be claimed for CERs. In such a case, the project emission calculation requires the carbon

---

12 This includes GHGs listed in Annex A of the Kyoto Protocol as well as GHGs controlled under the Montreal Protocol.

13 Either because the less carbon-intensive fuel used in the project building units was commercially available in the project boundary in the last five years, or there is no fuel switching measure involved in the project activity.
intensity of fuel energy used in the project building units to be the same as the one in the baseline. With this adjustment, however, emission reductions from energy efficiency measures can still be deemed additional as long as the total emissions level from the building units constructed in the project activity is lower than the baseline emissions level calculated by the benchmark analysis.

**Baseline emissions**

1. **Step 1: Identification of building unit categories**
2. **Step 2: Identification of baseline building units**
3. **Step 3: Calculation of emissions of each baseline building unit**
   - Due to electricity consumption
   - Due to fuel consumption
   - Due to chilled/hot water consumption
   - Due to the use of refrigerant(s)
   - Calculation of specific emissions of baseline building units
4. **Step 4: Calculation of top 20% benchmark for specific emissions of baseline building units**
   - Selection of top 20% performer building units
   - Calculation of top 20% benchmark

   - If there are no applicable and enforced standards in host country
   - If there are applicable and enforced standard in host country
5. **Step 5: Calculation of baseline emissions based on the top 20% benchmark**
6. **Step 6: Update of the baseline emission calculation**
Step 1: Identification of building unit categories

In the project activity, building units can be categorized into different categories. Building unit categories represent a wide range of uses and are very specific to the project circumstances. This methodology provides a mandatory list of building unit categories for use in Annex 1. The chosen categories shall be clearly presented in the PDD, and remain the same for the entire crediting period(s) unless a request for approval of changes is made according to the latest version of “Procedures for notifying and requesting approval of changes from the project activity as described in the registered project design document”.

Step 2: Identification of baseline building units

Baseline building units shall be identified for each building unit category $i$ defined in Step 1. The baseline building units are identified as building units in circumstances similar to the building units constructed in the project activity (project building units). In order to ensure similarity between the baseline and the project building units, the baseline building units shall consist of building units in building unit category $i$:

- That do not belong to a registered CDM project activity using this methodology;
- That are located in the same municipality as the project building units. If the minimum sample size of baseline building units cannot be obtained within the municipality, the project boundary should be extended to cover all neighboring municipalities. If the minimum sample size cannot still be obtained, the project boundary should be extended by including the geographical area of the next higher level of administrative boundary (e.g. state, province, prefecture, county). If the sample size still remains below the minimum size, the building unit category should be excluded;
- That have been built and then occupied within the five years prior to the start of the project activity;
- That are located in a region with annual heating degree days (HDD) and cooling degree days (CDD) in a range from 80% to 120% of the average value of the region that the project building units are located in;\(^{14}\)
- That are located in an area with similar socio-economic conditions to the one in which the project building units are located.
  - Acceptable data sources on the socio-economic conditions include: (a) income level information collected from a survey; (b) government records on income levels (e.g. for tax purposes); (c) relevant studies or publications on income levels, and/or (d) property prices per squared metre as a proxy for income levels.\(^{15}\) If no data or only limited data is publicly available on the socio-economic conditions, a survey can be conducted. The survey may limit its scope to building units that have been built in the project boundary within the five years prior to the start of the project activity.\(^{16}\) A minimum of three socio-economic classes should be defined based on the level of income or property price (e.g. low, middle, and high

\(^{14}\) This requirement is assumed to be determined, ex ante, by observation or review of public records but not by baseline building occupant surveys.

\(^{15}\) The project participants applying the methodology may submit a request for revision if the criteria for socio-economic conditions do not work for the project-specific situation.

\(^{16}\) If income level information is to be collected, a building unit needs to be occupied at the time of conducting the survey. If property price information is to be collected, it is not necessary for a building unit to be occupied.
income/property price groups). The approaches and underlying assumptions used to distinguish the socio-economic classes shall be transparently documented in the PDD;

- In case building units of a specific socio-economic class are concentrated in distinct areas, the baseline building units shall be chosen from areas with the same socio-economic class(es) as the project building units;

- In case building units with two or more socio-economic classes are located in the same area, individual building units need to be surveyed and building units of the same socio-economic class as the project building units shall be chosen. Alternatively, such an area with mixed socio-economic classes may be excluded from the baseline building unit selection as long as the minimum sample size can be obtained from other areas with a distinct socio-economic class;

- That have a comparable size to the project building units, defined as the GFA of a baseline building unit being in the range from 50% to 150% of the average GFA of the project building units in building unit category \( i \);

- That are occupied, and used as a primary, year-round residence (applicable only to residential building units, either in a low-rise or high-rise building);

- That are operated on annual average at least 30 hours/week (applicable only to commercial and institutional building units, either in a low-rise or high-rise building).

The project participants may either choose to identify the baseline building units from all the building units in the project boundary or use a randomly selected sample of the building units in the project boundary.

If the random sampling approach is used, emission reductions can be claimed only if the sample size is larger than the minimum sample size as determined below (\( n_{BL,min,i,y} \)). However, if the project has fewer building units than the minimum sample size in the corresponding building unit category \( i \), then the equivalent number of baseline building units can be used. This minimum number refers to the number of baseline building units, for which useful monitoring data are available in a particular monitoring time interval. Therefore, to compensate for any possible dropouts from the sample group during the monitoring period, it will be necessary to select an initial sample size. This minimum sample size should be the minimum value between project building units in building unit category \( i \) or 60. Project participants may choose any larger sample than the minimum sample size, taking into account the risk of dropouts from the sample group, the overhead costs for monitoring and the effect of reduced statistical errors on account of a larger sample size in calculating emission reductions. Different sample sizes may be selected for each vintage year as long as the sample sizes are larger than the minimum size.

\[
N_{BL,min,i,y} = \frac{cv_{SE,BL,i,y}^2 \times t_{0.05}^2 \times N_{BL,i}}{P_{10\%}^2 \times N_{BL,i} + cv_{SE,BL,i,y}^2 \times t_{0.05}^2}
\]  

\( ^{17} \) A building unit is considered to be in operation for the amount of hours the building unit is utilized for its main purpose (e.g. office work for an office building unit). The building unit might as well consume energy in other hours (e.g. standby energy consumption in the building unit during night time). However, those hours are not counted towards the operating hours.
Where:

\[ n_{BL,\text{min},i,y} = \text{Minimum sample size of baseline building units in building unit category } i \text{ in year } y. \]

Round up to the next integer if it is decimal

\[ \text{cv}_{SE,BL,i,y} = \text{Coefficient of variation of specific emissions of baseline building units in building unit category } i \text{ in year } y \]

\[ t_{0.05} = \text{t-value for a 90% statistical significance level (1.645)} \]

\[ P_{10\%} = 10\% \text{ precision requirement for a sample estimate (0.10)} \]

\[ N_{BL,i} = \text{Total number of baseline building units in the population for building unit category } i \text{ at the start of the project activity} \]

\[ \text{cv}_{SE,BL,i,y} = \frac{\sigma_{POP,SE,BL,i,y}}{\mu_{POP,SE,BL,i,y}} \] (2)

Where:

\[ \text{cv}_{SE,BL,i,y} = \text{Coefficient of variation of specific emissions of baseline building units in building unit category } i \text{ in year } y \]

\[ \sigma_{POP,SE,BL,i,y} = \text{Expected population standard deviation of specific emissions of baseline building units in building unit category } i \text{ in year } y \text{ (tCO}_2/\text{m}^2) \]

\[ \mu_{POP,SE,BL,i,y} = \text{Expected population mean of specific emissions of baseline building units in building unit category } i \text{ in year } y \text{ (tCO}_2/\text{m}^2) \]

\[ \text{cv}_{SE,BL,i,y} \] is a measure of the expected variation in specific emissions of the population of baseline building units in building unit category \( i \). For the first year, \( \text{cv}_{SE,BL,i,y} \) can be derived from officially published documents or own non-representative survey, accounting for the same emission sources as ones for the emission reduction calculation of the project activity. However, as necessary information may not be readily available, a default factor of 0.5 is allowed to be used for the first year. For the second year and onwards, \( \text{cv}_{SE,BL,i,y} \) needs to be replaced by the coefficient of variation of specific emissions of baseline building units calculated for the first year (\( \text{cv}_{SE,PJ,i,1} \)).

For the baseline building units in building unit category \( i \), the baseline emissions have to be calculated separately for each building unit category \( i \) for each crediting period year. If the random sampling approach is pursued, project participants shall first establish a list of all building units in the project boundary that meet all the relevant criteria for baseline building unit identification. If a complete list of building units cannot be established, project participants shall explain in the PDD reasons for non-availability of certain building units and justify why the available building units are considered representative of all building units in the project boundary. Then, a unique identifier is to be assigned to each building unit on the list for a random selection of building units. For example, such a random selection can be performed with common spreadsheet software. The collection of the energy consumption data from the baseline building units may require apportionment of the energy consumption if it is monitored only at a whole building level.\(^\text{18}\) In this case, such energy consumption has to be apportioned following the procedure existent for the building, showing documented evidence of the procedure and the proof that the procedure has been applied consistently in the last three years. If such procedure is not available, apportion the energy consumption by the GFA that each tenant/owner in the building occupies.

\(^\text{18}\) For example, energy consumption for the operation of a central air conditioning system for a whole building may be metered only at a whole building level. In this case, the building manager (e.g. facility manager, landlord) may simply include the energy bill in the rent without providing energy consumption data to each tenant/owner.
Also, the use of a refrigerant(s) monitored only at a whole building level\(^{19}\) shall also be apportioned by the GFA of the building unit. Such apportionment can be mathematically expressed as follows:

\[
X_{BL,i,j,y} = X_{BL-Bldg,i,j,y} \times \frac{GFA_{BL,i,j,y}}{GFA_{BL-Bldg,i,j,y}}
\]

(3)

Where:

- \(X_{BL,i,j,y}\) = Baseline energy consumption (electricity, fossil fuel, or chilled water) or baseline emissions related to the use of a refrigerant(s) in baseline building unit \(j\) in building unit category \(i\) in year \(y\) (MWh, mass or volume unit, GJ, or t refrigerant/yr)
- \(X_{BL-Bldg,i,j,y}\) = Baseline energy consumption (electricity, fossil fuel, or chilled water) or baseline emissions related to the use of a refrigerant(s) in the whole building, which baseline building unit \(j\) in building unit category \(i\) belongs to, in year \(y\) (MWh, mass or volume unit, GJ, or t refrigerant/yr)
- \(GFA_{BL,i,j,y}\) = GFA of baseline building unit \(j\) in building unit category \(i\) in year \(y\) (m\(^2\))
- \(GFA_{BL-Bldg,i,j,y}\) = GFA of the whole building, which baseline building unit \(j\) in building unit category \(i\) belongs to, in year \(y\). Account for GFA of each building unit in the building, but not GFA of the common service areas outside the physical boundaries of the building units (m\(^2\))

**Step 3: Calculation of emissions of each baseline building unit**

First, calculate the annual emissions of each baseline building unit \(j\) in building unit category \(i\) identified in Step 2. For the sake of simplification and conservativeness, the relevant emissions source(s) can be excluded from the calculation of the baseline emissions during the time period for which relevant data is not available.

\[
BE_{i,j,y} = BE_{EC,i,j,y} + BE_{FC,i,j,y} + BE_{WC,i,j,y} + BE_{ref,i,j,y}
\]

(4)

Where:

- \(BE_{i,j,y}\) = Baseline emissions of baseline building unit \(j\) in building unit category \(i\) in year \(y\) (t CO\(_2\)e/yr)
- \(BE_{EC,i,j,y}\) = Baseline emissions from electricity consumption of baseline building unit \(j\) in building unit category \(i\) in year \(y\) (t CO\(_2\)/yr)
- \(BE_{FC,i,j,y}\) = Baseline emissions from fossil fuel consumption of baseline building unit \(j\) in building unit category \(i\) in year \(y\) (t CO\(_2\)/yr)
- \(BE_{WC,i,j,y}\) = Baseline emissions from chilled/hot water consumption of baseline building unit \(j\) in building unit category \(i\) in year \(y\) (t CO\(_2\)/yr)
- \(BE_{ref,i,j,y}\) = Baseline emissions from the use of a refrigerant(s) in baseline building unit \(j\) in building unit category \(i\) in year \(y\) (t CO\(_2\)e/yr)

If it is justified that the CDM project activity does not result in an increase of emissions from the use of refrigerant(s) in buildings and the project emissions from the use of a refrigerant(s) is omitted from the calculation of the project emissions, \(BE_{ref,i,j,y}\) shall be excluded.

\(^{19}\) For example, the refrigerant use in a central air conditioner supplying the entire building.
Sub-step 3.1: Calculation of baseline emissions from electricity consumption ($BE_{EC,i,j,y}$)

The baseline emissions from electricity consumption of baseline building unit $j$ in building unit category $i$ ($BE_{EC,i,j,y}$) are further divided into the following two components:

$$BE_{EC,i,j,y} = BE_{EC,\text{non-REcaptive},i,j,y} + BE_{EC,\text{REcaptive},i,j,y}$$ (5)

Where:

- $BE_{EC,i,j,y}$ = Baseline emissions from electricity consumption of baseline building unit $j$ in building unit category $i$ in year $y$ (t CO$_2$/yr)
- $BE_{EC,\text{non-REcaptive},i,j,y}$ = Baseline emissions from electricity consumption of baseline building unit $j$ in building unit category $i$ in year $y$, which is supplied by the grid and/or an off-grid fossil-fuel-fired captive power plant(s) (t CO$_2$/yr)
- $BE_{EC,\text{REcaptive},i,j,y}$ = Baseline emissions from electricity consumption of baseline building unit $j$ in building unit category $i$ in year $y$, which is supplied by an off-grid renewable captive power plant(s) (t CO$_2$/yr)

$BE_{EC,\text{non-REcaptive},i,j,y}$ shall be calculated using the latest approved version of the “Tool to calculate baseline, project and/or leakage emissions from electricity consumption”.

$BE_{EC,\text{REcaptive},i,j,y}$ equals 0 (t CO$_2$/yr) as a conservative simplification.

Sub-step 3.2: Calculation of baseline emissions from fuel consumption ($BE_{FC,i,j,y}$)

The baseline emissions from fossil fuel consumption of baseline building unit $j$ in building unit category $i$ in year $y$ ($BE_{FC,i,j,y}$) shall be calculated as follows:

$$BE_{FC,i,j,y} = \sum_k FC_{BL,i,j,k,y} \times COEF_{k,y}$$ (6)

Where:

- $BE_{FC,i,j,y}$ = Baseline emissions from fossil fuel consumption of baseline building unit $j$ in building unit category $i$ in year $y$ (t CO$_2$/yr)
- $FC_{BL,i,j,k,y}$ = Annual consumption of fossil fuel type $k$ of baseline building unit $j$ in building unit category $i$ in year $y$. The amount of fuel used for the electricity generation by the captive power plant(s) in the building that baseline building unit $j$ belongs to shall not be included in the parameter (mass or volume unit/yr)
- $COEF_{k,y}$ = CO$_2$ emission coefficient of fuel type $k$ in year $y$ (t CO$_2$/mass or volume unit)

The CO$_2$ emission coefficient $COEF_{k,y}$ can be calculated using one of the following two options. Option A should be the preferred approach, if the necessary data is available.

Option A: The CO$_2$ emission coefficient $COEF_{i,y}$ is calculated based on the ultimate analysis of the fossil fuel type $k$, using the following approach:

If $FC_{BL,i,j,k,y}$ is measured in a mass unit: $COEF_{k,y} = w_{c,k,y} \times 44/12$ (7)

If $FC_{BL,i,j,k,y}$ is measured in a volume unit: $COEF_{k,y} = w_{c,k,y} \times \rho_{k,y} \times 44/12$ (8)
Where:

\[ \text{COEF}_{k,y} = \text{CO}_2 \text{ emission coefficient of fuel type } k \text{ in year } y \text{ (t CO}_2/\text{mass or volume unit)} \]

\[ w_{C,k,y} = \text{Mass fraction of carbon in fuel type } k \text{ in year } y \text{ (t C/mass unit of the fuel)} \]

\[ \rho_{k,y} = \text{Density of fuel type } k \text{ in year } y \text{ (mass unit/volume unit of the fuel)} \]

**Option B:** The \( \text{CO}_2 \) emission coefficient \( \text{COEF}_{k,y} \) is calculated based on the net calorific value and \( \text{CO}_2 \) emission factor of the fuel type \( k \), using the following approach:

\[ \text{COEF}_{k,y} = \text{NCV}_{k,y} \times \text{EF}_{\text{CO}_2,k,y} \]  \hspace{1cm} (9)

Where:

\[ \text{COEF}_{k,y} = \text{CO}_2 \text{ emission coefficient of fuel type } k \text{ in year } y \text{ (t CO}_2/\text{mass or volume unit)} \]

\[ \text{NCV}_{k,y} = \text{Average net calorific value of fossil fuel type } k \text{ used in year } y \text{ (GJ/mass or volume unit)} \]

\[ \text{EF}_{\text{CO}_2,k,y} = \text{CO}_2 \text{ emission factor of fossil fuel type } k \text{ in year } y \text{ (GJ/mass or volume unit)} \]

**Sub-step 3.3: Calculation of baseline emissions from chilled/hot water consumption \((\text{BE}_{\text{WC},i,j,y})\)**

The chilled/hot water systems for baseline building units applicable under this methodology should have following configuration. The equations are derived considering this configuration in account.\(^{20}\)

![Figure 1: The applicable configuration of chilled/hot water system](image)

The baseline emissions from chilled/hot water consumption of baseline building unit \( j \) in building unit category \( i \) in year \( y \) \((\text{BE}_{\text{WC},i,j,y})\) shall be calculated as follows:

\[ \text{BE}_{\text{WC},i,j,y} = \frac{\text{WC}_{\text{BL},i,j,y} \times \text{EF}_{\text{BL,WP},i,j,y}}{1 - \eta_{\text{BL,dist},i,j,y}} \]  \hspace{1cm} (10)

\(^{20}\) Project participants willing to allow different configuration of chilled/hot water systems for baseline building units should submit the request for revision to this methodology.
Where:

\[ BE_{WC,i,j,y} = \text{Baseline emissions from chilled/hot water consumption of baseline building unit } j \text{ in building unit category } i \text{ in year } y \ (t \text{ CO}_2/\text{yr}) \]

\[ WC_{BL,i,j,y} = \text{Energy content of annual chilled/hot water consumption in baseline building unit } j \text{ in building unit category } i \text{ in year } y \ (\text{GJ/yr}) \]

\[ EF_{BL,WP,i,j,y} = \text{Emission factor for production of chilled/hot water that is supplied to baseline building unit } j \text{ in building unit category } i \text{ in year } y \ (t \text{ CO}_2/\text{GJ}) \]

\[ \eta_{BL,dist,i,y} = \text{Average technical distribution losses of the chilled/hot water system } l \text{ network serving baseline building unit } j \text{ in building unit category } i \text{ in year } y \ (\text{GJ of technical thermal energy losses in the chilled/hot water distribution network divided by GJ of thermal energy supplied to the building units}) \]

If a heat meter(s) is installed for monitoring of the energy content of chilled/hot water consumed in the baseline building unit \( j \) (or centrally in the building that the baseline building unit belongs to), \( WC_{BL,i,j,y} \) can be derived directly from the meter reading. If only a mass or volume flow meter(s) and temperature indicators are installed, \( WC_{BL,i,j,y} \) is calculated according to the following equations:

\[ WC_{BL,i,j,y} = m_{BL,i,j,y} \times \Delta t_{BL,i,j,y} \times C_m \quad (11) \]

Where:

\[ WC_{BL,i,j,y} = \text{Energy content of annual chilled/hot water consumption in baseline building unit } j \text{ in building unit category } i \text{ in year } y \ (\text{GJ/yr}) \]

\[ m_{BL,i,j,y} = \text{Annual chilled/hot water consumption (in mass) of baseline building unit } j \text{ in building unit category } i \text{ in year } y \ (\text{kg/yr}) \]

\[ \Delta t_{BL,i,j,y} = \text{Average temperature difference between the outlet and inlet of the heat exchanger used for the cooling/heating of building unit } j \text{ in building unit category } i \text{ in year } y \ (\text{K}) \]

\[ C_m = \text{Specific heat capacity of the chilled/hot water (GJ/(kg·K))} \]

In case a volumetric flow meter, and not a mass flow meter, is installed, \( m_{BL,i,j,y} \) is calculated using the following equation:

\[ m_{BL,i,j,y} = v_{BL,i,j,y} \times \rho_{H2O} \quad (12) \]

Where:

\[ m_{BL,i,j,y} = \text{Annual chilled/hot water consumption (in mass) of baseline building unit } j \text{ in building unit category } i \text{ in year } y \ (\text{kg/yr}) \]

\[ v_{BL,i,j,y} = \text{Annual chilled/hot water consumption (in volume) of baseline building unit } j \text{ in building unit category } i \text{ in year } y \ (\text{m}^3/\text{yr}) \]

\[ \rho_{H2O} = \text{Density of the chilled/hot water (kg/m}^3) \]

The emission factor for chilled/hot water production \( (EF_{BL,WP,i,j,y}) \) shall be calculated for each centralised chilled/hot water system \( l \) that supplies the chilled/hot water to the respective building unit \( j \) in building unit category \( i \) in year \( y \), according to the following equation:

\[ EF_{BL,WP,i,j,y} = \frac{BE_{WP,EC,l,y} + BE_{WP,FC,l,y} + BE_{WP,FE,l,y}}{WP_{BL,l,y}} \quad (13) \]
Where:

\[ EF_{BL,WP,j,i,y} \] = Emission factor for production of chilled/hot water that is supplied to baseline building unit \( j \) in building unit category \( i \) in year \( y \) (t CO\(_2\)/GJ)

\[ BE_{WP,EC,l,y} \] = Baseline emissions from electricity consumption of chilled/hot water system \( l \) in year \( y \) (t CO\(_2\)/yr)

\[ BE_{WP,FC,l,y} \] = Baseline emissions from fuel consumption of chilled/hot water system \( l \) in year \( y \) (t CO\(_2\)/yr) (In case all or part of the heat consumed in chilled/hot water system \( l \) is supplied by fossil fuel)

\[ BE_{WP,FE,l,y} \] = Baseline fugitive emissions of CO\(_2\) and methane due to release of non-condensable gases from geothermal sources in chilled/hot water production in chilled/hot water system \( l \) in year \( y \) (t CO\(_2\)/yr) (In case all or part of the heat consumed in chilled/hot water system \( l \) is supplied by a geothermal source)

\[ WP_{BL,l,y} \] = Energy content of annual chilled/hot water produced by chilled/hot water system \( l \) in year \( y \) (GJ/yr)

If a heat meter(s) is/are installed for monitoring of the energy content of chilled/hot water production in the chilled/hot water cooling system \( l \), \( WP_{BL,l,y} \) can be derived directly from the meter reading. If only a mass or volume flow meter(s) is installed, \( WP_{BL,l,y} \) is calculated according to the following equations:

\[ WP_{BL,l,y} = m_{BL,l,y} \times \Delta t_{BL,l,y} \times C_m \]  \tag{14}

Where:

\[ WP_{BL,l,y} \] = Energy content of annual chilled/hot water production of chilled/hot water system \( l \) in year \( y \) (GJ/yr)

\[ m_{BL,l,y} \] = Annual chilled/hot water production (in mass) of chilled/hot water system \( l \) in year \( y \) (kg/yr)

\[ \Delta t_{BL,l,y} \] = Average temperature difference between the outlet and inlet of the heat exchanger used for the chilled/hot water production in chilled/hot water system \( l \) in year \( y \) (K)

\[ C_m \] = Specific heat capacity of the chilled/hot water (GJ/(kg·K))

In case a volumetric flow meter, and not a mass flow meter, is installed, \( m_{BL,l,y} \) is calculated using the following equation:

\[ m_{BL,l,y} = v_{BL,l,y} \times \rho_{H2O} \]  \tag{15}

Where:

\[ m_{BL,l,y} \] = Annual chilled/hot water production (in mass) of chilled/hot water system \( l \) in year \( y \) (kg/yr)

\[ v_{BL,l,y} \] = Annual chilled/hot water production (in volume) of chilled/hot water system \( l \) in year \( y \) (m\(^3\)/yr)

\[ \rho_{H2O} \] = Density of the chilled/hot water (kg/m\(^3\))

The baseline emissions from electricity consumption of chilled/hot water system \( l \) in year \( y \) (\( BE_{WP,EC,l,y} \)) shall be calculated using the “Tool to calculate baseline, project and/or leakage emissions from electricity consumption”. The electricity consumption includes the consumption all electrical equipment as a part of central chilled/hot water system e.g. compressor, pumps etc.
The baseline emissions from fossil fuel consumption of chilled/hot water system $l$ in year $y$ ($BE_{WP,FC,l,y}$) are calculated as follows:

$$BE_{WP,FC,l,y} = \sum_k FC_{BL,l,k,y} \times COEF_{k,y}$$  

(16)

Where:

- $BE_{WP,FC,l,y} =$ Baseline emissions from fossil fuel consumption of chilled/hot water system $l$ in year $y$ (t CO$_2$/yr)
- $FC_{BL,l,k,y} =$ Quantity of fossil fuel type $k$ fired in chilled/hot water system $l$ in year $y$ (mass or volume unit/yr)
- $COEF_{k,y} =$ CO$_2$ emission coefficient of fuel type $k$ in year $y$ (t CO$_2$/mass or volume unit)

The CO$_2$ emission coefficient $COEF_{k,y}$ shall be calculated following the same procedures as in the calculation of $BE_{FC,i,j,y}$ above using either option A or B (equations (7) to (9)).

In case all or part of the heat consumed in chilled/hot water system $l$ is supplied by a geothermal source, the fugitive emissions from these sources are calculated as follows:

$$BE_{WP,FE,l,y} = (w_{BL,steam,CO2,l,y} + w_{BL,steam,CH4,l,y} \times GWP_{CH4}) \times M_{BL,steam,l,y}$$  

(17)

Where:

- $BE_{WP,FE,l,y} =$ Baseline fugitive emissions of CO$_2$ and methane due to release of non-condensable gases from geothermal sources in chilled/hot water production in chilled/hot water system $l$ in year $y$ (t CO$_2$/yr)
- $w_{BL,steam,CO2,l,y} =$ Average mass fractions of carbon dioxide in the produced steam for the use in chilled/hot water system $l$ in year $y$ (t CO$_2$/t steam)
- $w_{BL,steam,CH4,l,y} =$ Average mass fractions of methane in the produced geothermal steam for the use in chilled/hot water system $l$ in year $y$ (t CH$_4$/t steam)
- $GWP_{CH4} =$ Global Warming Potential of methane valid for the relevant commitment period (t CO$_2$/tCH$_4$)
- $M_{BL,steam,l,y} =$ Quantity of geothermal steam produced for the use in chilled/hot water cooling system $l$ in year $y$ (t/yr)

Sub-step 3.4: Calculation of baseline emissions from the use of a refrigerant(s) ($BE_{ref,i,j,y}$)

The emissions from the use of a refrigerant(s) in baseline building unit $j$ in building unit category $i$ in year $y$ ($BE_{ref,i,j,y}$) shall be calculated as follows:

$$BE_{ref,i,j,y} = \sum_m Q_{BL,ref,i,j,m,y} \times GWP_{BL,ref,i,j,m,y} + BE_{WP,ref,l,y} \times \frac{WC_{BL,i,j,y}}{\left(1 - \eta_{BL,dist,l,y}\right) \times WP_{BL,i,j,y}}$$  

(18)

Where:

- $BE_{ref,i,j,y} =$ Baseline emissions from the use of a refrigerant(s) in baseline building unit $j$ in building unit category $i$ in year $y$ (t CO$_2$/yr)
- $Q_{BL,ref,i,j,m,y} =$ Annual quantity of refrigerant type $m$ used to replace the refrigerant(s) that has leaked in baseline building unit $j$ in building unit category $i$ in year $y$, excluding refrigerant leakage from chilled water system (t refrigerant/yr)
\[ \text{GWP}_{\text{BL,ref},i,m,y} = \text{Global Warming Potential of refrigerant type } m \text{ used in baseline building unit } j \text{ in building unit category } i \text{ in year } y \text{ (t CO}_2\text{e/t refrigerant)} \]
\[ \text{WC}_{\text{BL},i,j,y} = \text{Energy content of annual chilled water consumption in baseline building unit } j \text{ in building unit category } i \text{ in year } y \text{ (GJ/yr)} \]
\[ \text{BE}_{\text{WP,ref},l,y} = \text{Baseline emissions from the use of a refrigerant in chilled water system } l \text{ in year } y \text{ (t CO}_2\text{e/yr)} \]
\[ \eta_{\text{BL,dist},l,y} = \text{Average technical distribution losses of the chilled water system } l \text{ in year } y \text{ (GJ of technical thermal energy losses in the chilled water distribution network divided by GJ of thermal energy supplied to the building units)} \]
\[ \text{WP}_{\text{BL},l,y} = \text{Energy content of annual chilled water produced by chilled water system } l \text{ in year } y \text{ (GJ/yr)} \]

The baseline emissions from the use of a refrigerant in chilled water system \( l \) in year \( y \) (\( \text{BE}_{\text{WP,ref},l,y} \)) are calculated as follows:

\[ \text{BE}_{\text{WP,ref},l,y} = \text{Q}_{\text{BL,ref},l,y} \times \text{GWP}_{\text{BL,ref},l,y} \]  

(19)

Where:
\[ \text{BE}_{\text{WP,ref},l,y} = \text{Baseline emissions from the use of a refrigerant in chilled water system } l \text{ in year } y \text{ (t CO}_2\text{e/yr)} \]
\[ \text{Q}_{\text{BL,ref},l,y} = \text{Average annual quantity of the refrigerant used to replace the refrigerant that has leaked in chilled water system } l \text{ in year } y \text{ (t refrigerant/yr)} \]
\[ \text{GWP}_{\text{BL,ref},l,y} = \text{Global Warming Potential of the refrigerant used in chilled water system } l \text{ in year } y \text{ (t CO}_2\text{e/t refrigerant)} \]

**Sub-step 3.5: Calculation of specific emissions of baseline building units**

Calculate the specific emissions (SE) of baseline building unit \( j \) in building unit category \( i \) in year \( y \), defined as emissions per GFA in square metre per year:

\[ \text{SE}_{\text{BL},i,j,y} = \frac{\text{BE}_{i,j,y}}{\text{GFA}_{\text{BL},i,j,y}} \]  

(20)

Where:
\[ \text{SE}_{\text{BL},i,j,y} = \text{Specific emissions of baseline building unit } j \text{ in building unit category } i \text{ in year } y \text{, defined as emissions per GFA in square metre per year (t CO}_2\text{e/(m}^2\text{·yr))}} \]
\[ \text{BE}_{i,j,y} = \text{Baseline emissions of baseline building unit } j \text{ in building unit category } i \text{ in year } y \text{ (t CO}_2\text{e/yr)} \]
\[ \text{GFA}_{\text{BL},i,j,y} = \text{GFA of baseline building unit } j \text{ in building unit category } i \text{ in year } y \text{ (m}^2\text{)} \]

**Step 4: Calculation of the top 20% benchmark for specific emissions of baseline building units**

**Sub-step 4.1: Selection of the top 20% performer building units**

Sort the group of the baseline building units from the lowest to the highest specific energy consumption (SE). Identify the top 20% performer building units \( j \) as the building units with the 1\(^{\text{st}}\) to \( J\(^{\text{th}}\) lowest SE, where \( J \) (the total number of top 20% performer building units \( j \)) is calculated as the product of the number of baseline building units monitored and 20%, rounded down to the next integer if it is decimal.
Sub-step 4.2: Calculation of top 20% benchmark

Sub-step 4.2.a: Follow this step if there are no applicable and enforced standards on building energy efficiency in the host country

SEs of the top 20% performer building units ($SE_{Top20\%\_i\_j\_y}$) is averaged to determine the top 20% benchmark level of SE for baseline building units in building unit category $i$ in year $y$ ($SE_{Top20\%\_i\_y}$).

\[
SE_{Top20\%\_i\_y} = \frac{\sum_j SE_{Top20\%\_i\_j\_y}}{J_{i\_y}}
\]  

(21)

Where:

$SE_{Top20\%\_i\_y}$ = Specific emissions of the top 20% performer building units in building unit category $i$ in year $y$, defined as emissions per GFA in square meter per year (t CO$_2$/m$^2$·yr))

$SE_{Top20\%\_i\_j\_y}$ = Specific emissions of top 20% performer building unit $j$ in building unit category $i$ in year $y$, defined as emissions per GFA in square meter per year (t CO$_2$/m$^2$·yr))

$J_{i\_y}$ = Total number of the top 20% performer building units in building unit category $i$ in year $y$. It is calculated as the product of the number of baseline building units monitored in building category $i$ and 20%, rounded down to the next integer if it is decimal

If sampling of the baseline building units is involved in the calculation of SE of the baseline building units, the calculated $SE_{Top20\%\_i\_y}$ shall be conservatively adjusted for the sampling error. Namely, the adjustment requires $SE_{Top20\%\_i\_y}$ to be the lower-bound value of the confidence interval established around the average SE of the top 20% performer building units at a 90% significance level. This sample error adjustment is performed by a bootstrap method. First, create resamples of $SE_{BL\_i\_j\_y}$ by repeatedly sampling at random and with replacement from the original sample of $SE_{BL\_i\_j\_y}$. Each resample is the same size as the original sample and the minimum size of the resamples is 1,000. Second, create a bootstrap distribution calculating $SE_{Top20\%\_i\_y}$ for each resample according to the equation (21). Lastly, the sample-error-adjusted $SE_{Top20\%\_i\_y}$ is the value of $SE_{Top20\%\_i\_y}$ at the 5th percentile of the bootstrap distribution.

Sub-step 4.2.b: Follow this step if there is an applicable and enforced standard on building energy efficiency in the host country

The building energy efficiency levels stipulated in the standard shall be the basis of the calculation of $SE_{Top20\%\_i\_y}$. For this purpose, $SE_{Top20\%\_i\_y}$ is divided into the following components:

\[
SE_{Top20\%\_i\_y} = EL_{Standard\_i\_y} \times CI_{Top20\%\_i\_y} + REFI_{Top20\%\_i\_y}
\]  

(22)

---

21 Refer to Hesterberg et al. (2005) for more details of the bootstrap method.

22 Sampling with replacement means that after randomly drawing an observation from the original sample, it is put back before drawing the next observation.
Where:

- **SE\text{Top20\%},i,y** = Specific emissions of top 20% performer building units in building unit category *i* in year *y*, defined as emissions per GFA in square metre per year (t CO\(_2\)/m\(^2\)-yr)
- **EI\text{Standard},i,y** = Energy efficiency of building units in building unit category *i* stipulated in an applicable and enforced standard on building energy efficiency in the host country (MWh/(m\(^2\)-yr))
- **CI\text{Top20\%},i,y** = Average carbon intensity of energy used in the top 20% performer building units in building unit category *i* in year *y* (t CO\(_2\)/MWh)
- **REFI\text{Top20\%},i,y** = Specific emissions from the use of a refrigerant(s) in the top 20% performer building units in building unit category *i* in year *y* (t CO\(_2\)/m\(^2\)-yr)

**Note:** The minimum between the value of SE\text{Top20\%},i,y calculated using equation 21 and 22 should be used under this option.

The average carbon intensity of energy used in the top 20% performer building units (CI\text{Top20\%},i,y) is calculated as follows:

\[
CI_{\text{Top20\%},i,y} = \frac{\sum CI_{\text{Top20\%},j,y}}{J_{i,y}} \tag{23}
\]

Where:

- **CI\text{Top20\%},i,y** = Average carbon intensity of energy used in the top 20% performer building units in building unit category *i* in year *y* (t CO\(_2\)/MWh)
- **CI\text{Top20\%},i,j,y** = Carbon intensity of energy used in top 20% performer building unit *j* in building unit category *i* in year *y* (t CO\(_2\)/MWh)
- **J_{i,y}** = Total number of top 20% performer building units in building unit category *i* in year *y* (t CO\(_2\)/yr). It is calculated as the product of the number of baseline building units monitored in building category *i* and 20%, rounded down to the next integer if it is decimal

CI\text{Top20\%},i,j,y is a subset of carbon intensity of energy used in baseline building unit *j* in building unit category *i* in year *y* (CI\text{BL},i,j,y), which is calculated as follows:

\[
CI_{\text{BL},i,j,y} = \frac{BE_{\text{EC},i,j,y} + BE_{\text{FC},i,j,y} + BE_{\text{WC},i,j,y}}{EC_{\text{BL},i,j,y} + \left(\sum FC_{\text{BL},i,j,k,y} \times NCV_{k,y} + WC_{\text{BL},i,j,y}\right) \times 0.2778} \tag{24}
\]

Where:

- **CI\text{BL},i,j,y** = Carbon intensity of energy used in baseline building unit *j* in building unit category *i* in year *y* (t CO\(_2\)/MWh)
- **BE_{\text{EC},i,j,y}** = Baseline emissions from electricity consumption of baseline building unit *j* in building unit category *i* in year *y* (t CO\(_2\)/yr)
- **BE_{\text{FC},i,j,y}** = Baseline emissions from fossil fuel consumption of baseline building unit *j* in building unit category *i* in year *y* (t CO\(_2\)/yr)
- **BE_{\text{WC},i,j,y}** = Baseline emissions from chilled/hot water consumption of baseline building unit *j* in building unit category *i* in year *y* (t CO\(_2\)/yr)
EC_{BL,i,j,y} = Electricity consumption of baseline building unit j in building unit category i in year y (MWh/yr)

FC_{BL,i,j,k,y} = Annual consumption of fossil fuel type k of baseline building unit j in building unit category i in year y. The amount of fuel used for the electricity generation by the captive power plant(s) in the building that project building unit j belongs to shall not be included in the parameter (mass or volume unit/yr)

NCV_{k,y} = Average net calorific value of fossil fuel type k used in year y (GJ/mass or volume unit)

WC_{BL,i,j,y} = Energy content of annual chilled/hot water consumption in baseline building unit j in building unit category i in year y (GJ/yr)

0.2778 = A multiplication factor used to convert GJ to MWh

The average specific emissions from the use of a refrigerant(s) in the top 20% performer building units (REFI_{Top20%,i,j,y}) is calculated as follows:

$$\text{REFI}_{\text{Top20%},i,j,y} = \frac{\sum_j \text{REFI}_{\text{Top20%},i,j,y}}{J_{i,y}}$$

Where:

\text{REFI}_{\text{Top20%},i,j,y} = Average specific emissions from the use of a refrigerant(s) in the top 20% performer building units in building unit category i in year y (t CO}_2/(m^2·yr))

\text{REFI}_{\text{Top20%},i,j,y} = Specific emissions from the use of a refrigerant(s) in top 20% performer building unit j in building unit category i in year y (t CO}_2/(m^2·yr))

J_{i,y} = Total number of top 20% performer building units in building unit category i in year y (t CO}_2/yr). It is calculated as the product of the number of baseline building units monitored in building category i and 20%, rounded down to the next integer if it is decimal

\text{REFI}_{\text{Top20%},i,j,y} is a subset of specific emissions from the use of a refrigerant(s) in baseline building unit j in building unit category i in year y (REFI_{BL,i,j,y}), which is calculated as follows:

$$\text{REFI}_{\text{BL},i,j,y} = \frac{\text{BE}_{\text{ref},i,j,y}}{\text{GFA}_{\text{BL},i,j,y}}$$

Where:

\text{REFI}_{\text{BL},i,j,y} = Specific emissions from the use of a refrigerant(s) in baseline building unit j in building unit category i in year y (t CO}_2/(m^2·yr))

\text{BE}_{\text{ref},i,j,y} = Baseline emissions from the use of a refrigerant(s) in baseline building unit j in building unit category i in year y (t CO}_2/yr)

\text{GFA}_{\text{BL},i,j,y} = GFA of baseline building unit j in building unit category i in year y (m^2)

If a sample of building units in the project boundary is monitored as baseline building units, the calculated CI_{Top20%},i,y and REFI_{Top20%},i,y shall be conservatively adjusted for the sampling error. Namely, the adjustment requires CI_{Top20%},i,y and REFI_{Top20%},i,y to be the lower-bound value of the confidence interval.
established around the average CI and REFI of the top 20% performer building units at a 90% significance level. This sample error adjustment is performed by a bootstrap method. First, create resamples of $\text{CI}_{BL,i,j,y}$ and $\text{REFI}_{BL,i,j,y}$ by repeatedly sampling at random and with replacement from the original sample of $\text{CI}_{BL,i,j,y}$ and $\text{REFI}_{BL,i,j,y}$. Each resample is the same size as the original sample and the minimum size of the resamples is 1,000. Second, create bootstrap distributions calculating $\text{CI}_{\text{Top20\%},i,y}$ and $\text{REFI}_{\text{Top20\%},i,y}$ for each resample according to the equations (23) and (25). Lastly, the sample-error-adjusted $\text{CI}_{\text{Top20\%},i,y}$ and $\text{REFI}_{\text{Top20\%},i,y}$ are the values of $\text{CI}_{\text{Top20\%},i,y}$ and $\text{REFI}_{\text{Top20\%},i,y}$ at the 5th percentile of the corresponding bootstrap distribution.

**Step 5: Calculation of baseline emissions based on the top 20% benchmark**

Based on the top 20% benchmark SE determined above, the baseline emissions are calculated by multiplying the top 20% benchmark SE by the total GFA of the project building units in the corresponding building unit category $i$. Accordingly, the total baseline emissions are calculated as follows:

$$\text{BE}_{y} = \sum_{i} \text{SE}_{\text{Top20\%},i,y} \times \text{GFA}_{PJ,i,y} \times \text{CF}_{BL,i,y} \times \text{DISC}_{i,y}$$  \hspace{1cm} (27)

Where:
- $\text{BE}_{y}$ = Baseline emissions of baseline building units in year $y$ (t CO$_2$/yr)
- $\text{SE}_{\text{Top20\%},i,y}$ = Specific emissions of top 20% performer building units in building unit category $i$ in year $y$, defined as emissions per unit GFA (in square meter) per year (t CO$_2$/m$^2$/yr))
- $\text{GFA}_{PJ,i,y}$ = Total GFA of project building units in building unit category $i$ in year $y$ (m$^2$)
- $\text{CF}_{BL,i,y}$ = Baseline correction factor for occupancy of project building units in building unit category $i$ in year $y$
- $\text{DISC}_{i,y}$ = Discount factor for double-counting of emissions reductions due to overlapping use of efficient appliances in building unit category $i$ in year $y$

The discount factor ($\text{DISC}_{i,y}$) is calculated as follows:

$$\text{DISC}_{i,y} = 1 - \sum_{n} \frac{\text{APPL}_{\text{CDM},n,y}}{\text{APPL}_{\text{Host},n,y}} \times \text{ESHARE}_{i,n}$$  \hspace{1cm} (28)

Where:
- $\text{DISC}_{i,y}$ = Discount factor for double-counting of emissions reductions due to overlapping use of efficient appliances in building unit category $i$ in year $y$
- $\text{APPL}_{\text{CDM},n,y}$ = Total number of efficient appliances of type $n$ that are used in registered CDM project(s) in the host country in year $y$
- $\text{APPL}_{\text{Host},n,y}$ = Total number of efficient appliances of type $n$ that are sold in the host country in year $y$
- $\text{ESHARE}_{i,n}$ = Default share of energy use of efficient appliances of type $n$ in the total building energy consumption in building unit category $i$ in year $y$

---

23 Refer to Hesterberg et al. (2005) for more details of the bootstrap method.

24 Sampling with replacement means that after randomly drawing an observation from the original sample, it is put back before drawing the next observation.
The baseline correction factor for occupancy of project building units (CF_{BL,i,y}) is set to one if all the building units in the project boundary are monitored as project building units. If a sample of building units in the project boundary is monitored as project building units, CF_{BL,i,y} shall be calculated as follows:

\[
CF_{BL,i,y} = 1 - \left( \lambda_{PJ,i,y} + t_{0.05} \times \sqrt{\frac{\lambda_{PJ,i,y} \times (1 - \lambda_{PJ,i,y})}{n_{PJ,i,y}}} \right)
\]  

(29)

Where:
- CF_{BL,i,y} = Baseline correction factor for occupancy of project building units in building unit category i in year y
- \lambda_{PJ,i,y} = Share of building units not meeting the occupancy criterion for project building units in building unit category i in year y
- t_{0.05} = t-value for a 90% statistical significance level (1.645)
- n_{PJ,i,y} = Total number of project building units included in the sample for building unit category i in year y

\[
\lambda_{PJ,i,y} = \frac{n_{PJ,UNO,i,y}}{n_{PJ,i,y}}
\]  

(30)

Where:
- \lambda_{PJ,i,y} = Share of building units not meeting the occupancy criterion for project building units in building unit category i in year y
- n_{PJ,UNO,i,y} = Total number of project building units not satisfying the occupancy criterion in the sample for building unit category i in year y. See Step 2 “Identification of project building units” for the occupancy criterion
- n_{PJ,i,y} = Total number of project building units included in the sample for building unit category i in year y

**Step 6: Update of the baseline emission calculation**

In order to reflect the changes in the energy consumption patterns of the baseline building units over time, the relevant data (EC_{BL,i,j,y}, FC_{BL,i,k,y} and WC_{BL,i,y}) shall be collected every year from the same baseline building units which are included in top 20% performers identified from the first year after project implementation. If a baseline building unit in the group of top 20% is destroyed or its function is changed, it can be replaced by another building unit in the same building unit category that is randomly sampled.

The calculation of the baseline emissions from the use of a refrigerant(s) (BE_{ref,i,j,y}) shall be updated annually for the building units which are included in the top 20% performers identified from the first year after project implementation. Alternatively, it can be updated for the first three years of the corresponding crediting period, and for any subsequent year in the crediting period, the minimum annual value of the three-year monitoring period can be used.

All the other baseline-related data need to be updated every third year (e.g. year 4, 7, 10) for the baseline building units that are included in the 20% performers identified from the first year after project implementation.
The total GFA of project building units in building unit category \( i \) in year \( y \) (GFA_{PJ,i,y}) has to be updated at least every third year (e.g. year 4, 7, 10), or more frequently, in order to reflect the change in the scale of the project activity over time.

Based on the above data, the baseline emissions shall be updated annually during project implementation for the baseline building units which are included in the top 20% performers identified from the first year after project implementation.

All the steps should be documented transparently, including a list of the baseline building units identified, with information to clearly identify the building units, as well as the relevant data used for the calculation of the baseline emissions.

**Project emissions**

1. **Identification of building unit categories**
2. **Identification of project building units**
3. **Calculation of emissions of each project building unit**
   - Due to electricity consumption
   - Due to fuel consumption
   - Due to chilled/hot water consumption
   - Due to the use of refrigerant(s)
   - Calculation of specific emissions of project building units
4. **Calculation of project emissions**
   - Fuel switching measures are demonstrated to be additional
   - Fuel switching measures are not demonstrated to be additional
5. **Update of the project emission calculation**

**Step 1: Identification of building unit categories**

The same building unit categories as the ones identified in Step 1 of the baseline emissions section shall be used. The definitions shall be clearly presented in the PDD, and remain the same for the entire crediting period(s) unless a request for approval of changes is made according to the latest version of the
“Procedures for notifying and requesting approval of changes from the project activity as described in the registered project design document”.

**Step 2: Identification of project building units**

Project building units shall be identified for each building unit category \( i \) defined in Step 1. The project building units shall consist of building units in building unit category \( i \), which satisfy the following occupancy criterion:

- That are occupied, and used as a primary, year-round residence (applicable only to residential building units, either in a low-rise or high-rise building);
- That are operated on annual average at least 30 hours/week (applicable only to commercial and institutional building units, either in a low-rise or high-rise building).

The compliance with the occupancy criterion needs to be monitored *ex post*, and project building units failing to satisfy the occupancy criterion shall be excluded from the pool of project building units \((N_{PJ,UNO,i,y} \text{ or } n_{PJ,UNO,i,y})\), whether the population or sample is monitored. If all the building units in the project boundary are monitored as project building units, the ex-post monitoring assures that the non-compliant project building units are not considered in the emission reduction calculation. If a sample of building units in the project boundary is monitored as project building units, excluding the non-compliant project building units does not ensure that there is no non-compliant project building unit in the population. Thus, the project and baseline emissions need to be corrected for the share of non-compliant project building units. For this purpose, the number of project building units not satisfying the occupancy criterion \((n_{PJ,UNO,i,y})\) is monitored *ex post*.

The project participants may either choose to identify the project building units as all the building units in the project boundary or use a randomly selected sample of the building units in the project boundary.

If the random sampling approach is used, emission reductions can be claimed only if the sample size is larger than the minimum sample size as determined below \((n_{PJ,min,i,y})\). This minimum number refers to the number of project building units, for which useful monitoring data are available in a particular monitoring interval. Therefore, to compensate for any possible dropouts from the sample group during the monitoring period, it will be necessary to initially select a sample size. Project participants may choose any size larger than the minimum sample size, taking into account the risk of dropouts from the sample group, the overhead costs for monitoring and the effect from reduced statistical errors on account of a larger sample size in calculating emission reductions. The minimum sample size needs to be updated every year because the total number of project building units for building unit category \( i \) may change over time. Different sample sizes may be chosen for each vintage year as long as the sample sizes are larger than the minimum size.

\[
n_{PJ,min,i,y} = \frac{c_{V,SE,PJ,i,y}^2 \times t_{0.05}^2 \times N_{PJ,i,y}}{\frac{P_{10\%}^2}{N_{PJ,i,y}} + c_{V,SE,PJ,i,y}^2 \times t_{0.05}^2}
\]

(31)

---

25 A building unit is considered to be in operation for the amount of hours the building unit is utilized for its main purpose (e.g. office work for an office building unit). The building unit might as well consume energy in other hours (e.g. standby energy consumption in the building unit during night time). However, those hours are not counted towards the operating hours.
Where:

\( n_{PJ,\text{min},i,y} \) = Minimum sample size of project building units in building unit category \( i \) in year \( y \).

\( \text{Round up to the next integer if it is decimal} \)

\( \text{cv}_{SE,PJ,i,y} \) = Coefficient of variation of specific emissions of project building units in building unit category \( i \) in year \( y \).

\( t_{0.05} \) = t-value for a 90% statistical significance level (1.645)

\( P_{10\%} \) = 10% precision requirement for a sample estimate (0.10)

\( N_{PJ,i,y} \) = Total number of project building units for building unit category \( i \) in year \( y \).

\[
\text{cv}_{SE,PJ,i,y} = \frac{\sigma_{POP,SE,PJ,i,y}}{\mu_{POP,SE,PJ,i,y}}
\]

(32)

Where:

\( \text{cv}_{SE,PJ,i,y} \) = Coefficient of variation of specific emissions of project building units in building unit category \( i \) in year \( y \).

\( \sigma_{POP,SE,PJ,i,y} \) = Expected population standard deviation of specific emissions of project building units in building unit category \( i \) in year \( y \) (tCO\(_2\)/m\(^2\))

\( \mu_{POP,SE,PJ,i,y} \) = Expected population mean of specific emissions of project building units in building unit category \( i \) in year \( y \) (tCO\(_2\)/m\(^2\)).

\( \text{cv}_{SE,PJ,i,y} \) is a measure of the expected variation in specific emissions of the population of project building units in building unit category \( i \) in year \( y \). For the first year, \( \text{cv}_{SE,PJ,i,y} \) can be derived from officially published documents or own non-representative survey, accounting for the same emission sources as ones for the emission reduction calculation of the project activity. However, as necessary there may not be information readily available, a default factor of 0.5 is allowed to be used for the first year. For the second year, \( \text{cv}_{SE,PJ,i,y} \) needs to be calculated based on the expected population mean and standard deviation of specific emissions of project building units in building unit category \( i \) in year \( y \) (\( \mu_{POP,SE,PJ,i,y} \) and \( \sigma_{POP,SE,PJ,i,y} \)). The sample mean and standard deviation of the same for the first year (\( \mu_{SE,PJ,i,1} \) and \( \sigma_{SE,PJ,i,1} \)), calculated with the equations (48) and (49), may be used as proxies for \( \mu_{POP,SE,PJ,i,y} \) and \( \sigma_{POP,SE,PJ,i,y} \). In case all the building units in the project boundary are monitored as project building units, replace \( n_{PJ,i,y} \) by \( N_{PJ,i,y} \) in using the equations (48) and (49).

For the project building units in building unit category \( i \), the project emissions have to be calculated separately for each building unit category \( i \) for each crediting period year. If the random sampling approach is pursued, the same procedures as the baseline building units sampling shall be followed.

The collection of the energy consumption data from the project building units may require apportionment of the energy consumption if it is monitored only at a whole building level. In this case, apportion the energy consumption by the GFA that each tenant/owner in the building occupies. Also, the use of a

---

26 Regardless of additionality or existence of the fuel switching measures, these equations may be used for the sample size determination purpose.

27 For example, energy consumption for the operation of a central air conditioning system for a whole building may be metered only at a whole building level. In this case, the building manager (e.g. facility manager, landlord) may simply include the energy bill in the rent without providing energy consumption data to each tenant.
refrigerant(s) monitored only at a whole building level\textsuperscript{28} shall also be apportioned by the GFA of the building unit. Such apportionment can be mathematically expressed as follows:

\[ X_{pj,i,j,y} = X_{pj-bldg,i,j,y} \times \frac{\text{GFA}_{pj,i,j,y}}{\text{GFA}_{pj-bldg,i,j,y}} \] (33)

Where:
\[ X_{pj,i,j,y} = \text{Project energy consumption (electricity, fossil fuel, or chilled water) or project emissions related to use of a refrigerant(s) in project building unit } j \text{ in building unit category } i \text{ in year } y \text{ (MWh, mass or volume unit, GJ, or t refrigerant/yr)} \]
\[ X_{pj-bldg,i,j,y} = \text{Project energy consumption (electricity, fossil fuel, or chilled water) or project emissions related to the use of a refrigerant(s) in the whole building, which project building unit } j \text{ in building unit category } i \text{ belongs to, in year } y \text{ (MWh, mass or volume unit, GJ, or t refrigerant/yr)} \]
\[ \text{GFA}_{pj,i,j,y} = \text{GFA of project building unit } j \text{ in building unit category } i \text{ in year } y \text{ (m}^2\text{)} \]
\[ \text{GFA}_{pj-bldg,i,j,y} = \text{GFA of the whole building, which project building unit } j \text{ in building unit category } i \text{ belongs to, in year } y. \text{ Account for GFA of each building unit in the building, but not GFA of the common service areas outside the physical boundaries of the building units (m}^2\text{)} \]

**Step 3: Calculation of emissions of each project building unit**

First, calculate the annual emissions of each project building unit \(j\) in building unit category \(i\) identified in Step 2.

\[ \text{PE}_{i,j,y} = \text{PE}_{EC,i,j,y} + \text{PE}_{FC,i,j,y} + \text{PE}_{WC,i,j,y} + \text{PE}_{ref,i,j,y} \] (34)

Where:
\[ \text{PE}_{i,j,y} = \text{Project emissions of project building unit } j \text{ in building unit category } i \text{ in year } y \text{ (t CO}_2\text{e/yr)} \]
\[ \text{PE}_{EC,i,j,y} = \text{Project emissions from electricity consumption of project building unit } j \text{ in building unit category } i \text{ in year } y \text{ (t CO}_2\text{e/yr)} \]
\[ \text{PE}_{FC,i,j,y} = \text{Project emissions from fossil fuel consumption of project building unit } j \text{ in building unit category } i \text{ in year } y \text{ (t CO}_2\text{e/yr)} \]
\[ \text{PE}_{WC,i,j,y} = \text{Project emissions from chilled/hot water consumption of project building unit } j \text{ in building unit category } i \text{ in year } y \text{ (t CO}_2\text{e/yr)} \]
\[ \text{PE}_{ref,i,j,y} = \text{Project emissions from the use of a refrigerant(s) in project building unit } j \text{ in building unit category } i \text{ in year } y \text{ (t CO}_2\text{e/yr)} \]

If it is justified that the CDM project activity does not result in an increase of emissions from the use of a refrigerant(s) in buildings as compared to the baseline, \(\text{PE}_{ref,i,j,y}\) may be excluded.

\textsuperscript{28} E.g. the refrigerant use in a central air conditioner supplying the entire building.
**Sub-step 3.1: Calculation of project emissions from electricity consumption (PE_{EC,i,j,y})**

The project emissions from electricity consumption of project building unit $j$ in building unit category $i$ ($PE_{EC,i,j,y}$) are further divided into the following two components:

$$PE_{EC,i,j,y} = PE_{EC,non-REcaptive,i,j,y} + PE_{EC,REcaptive,i,j,y}$$ \quad (35)

Where:

- $PE_{EC,i,j,y}$ = Project emissions from electricity consumption of project building unit $j$ in building unit category $i$ in year $y$ (t CO\textsubscript{2}/yr)
- $PE_{EC,non-REcaptive,i,j,y}$ = Project emissions from electricity consumption of project building unit $j$ in building unit category $i$ in year $y$, which is supplied by the grid and/or an off-grid fossil-fuel-fired captive power plant(s) (t CO\textsubscript{2}/yr)
- $PE_{EC,REcaptive,i,j,y}$ = Project emissions from electricity consumption of project building unit $j$ in building unit category $i$ in year $y$, which is supplied by an off-grid renewable captive power plant(s) (t CO\textsubscript{2}/yr)

$PE_{EC,non-REcaptive,i,j,y}$ shall be calculated using the latest approved version of the “Tool to calculate baseline, project and/or leakage emissions from electricity consumption”.

$PE_{EC,REcaptive,i,j,y}$ equals 0 (t CO\textsubscript{2}/yr) as the methodology excludes the use of biogas or biomass systems.

**Sub-step 3.2: Calculation of project emissions from fuel consumption (PE_{FC,i,j,y})**

The project emissions from fossil fuel consumption of project building unit $j$ in building unit category $i$ in year $y$ ($PE_{FC,i,j,y}$) shall be calculated using the latest approved version of the “Tool to calculate project or leakage CO\textsubscript{2} emissions from fossil fuel combustion”.

**Sub-step 3.3: Calculation of project emissions from chilled/hot water consumption (PE_{WC,i,j,y})**

The chilled/hot water systems installed in project building units applicable under this methodology should have configuration as depicted in figure 1. The equations are derived considering this configuration in account.\textsuperscript{29}

The project emissions from chilled/hot water consumption of project building unit $j$ in building unit category $i$ in year $y$ ($PE_{WC,i,j,y}$) shall be calculated as follows:

$$PE_{WC,i,j,y} = \frac{WC_{PJ,i,j,y} \times EF_{PJ,WP,i,j,y}}{1 - \eta_{PJ,dist.,i,j,y}}$$ \quad (36)

Where:

- $PE_{WC,i,j,y}$ = Project emissions from chilled/hot water consumption of project building unit $j$ in building unit category $i$ in year $y$ (t CO\textsubscript{2}/yr)
- $WC_{PJ,i,j,y}$ = Energy content of annual chilled/hot water consumed in project building unit $j$ in building unit category $i$ in year $y$ (GJ/yr)

\textsuperscript{29} Project participants willing to use a different configuration of chilled/hot water systems in project buildings should submit the request for revision to this methodology.
EF_{PJ,WP,i,j,y} = \text{Emission factor for production of chilled/hot water that is supplied to project unit } j \text{ in building unit category } i \text{ in year } y \text{ (t CO}_2/\text{GJ)}

\eta_{PJ,\text{dist},l,y} = \text{Average technical distribution losses of the chilled/hot water system } l \text{ in year } y \text{ (GJ of thermal energy losses in the chilled/hot water distribution network divided by GJ of thermal energy supplied to the building units)}

If a heat meter(s) is installed for monitoring of the energy content of chilled/hot water consumed in the project building unit \( j \) (or centrally in the building that the project building unit belongs to), \( WC_{PJ,i,j,y} \) can be derived directly from the meter reading. If only a mass or volume flow meter(s) and temperature indicators are installed, \( WC_{PJ,i,j,y} \) is calculated according to the following equations:

\[
WC_{PJ,i,j,y} = m_{PJ,i,j,y} \times \Delta t_{PJ,i,j,y} \times C_m \tag{37}
\]

Where:

- \( WC_{PJ,i,j,y} \) = Energy content of annual chilled/hot water consumption in project building unit \( j \) in building unit category \( i \) in year \( y \) (GJ/yr)
- \( m_{PJ,i,j,y} \) = Annual chilled/hot water consumption (in mass) of project building unit \( j \) in building unit category \( i \) in year \( y \) (kg/yr)
- \( \Delta t_{PJ,i,j,y} \) = Average temperature difference between the outlet and inlet of the heat exchanger used for the cooling and heating of building unit \( j \) in building unit category \( i \) in year \( y \) (K)
- \( C_m \) = Specific heat capacity of the chilled water (GJ/(kg·K))

In case the volumetric flow meter, and not mass flow meter, is installed, \( m_{PJ,i,j,y} \) is calculated using the following equation.

\[
m_{PJ,i,j,y} = v_{PJ,i,j,y} \times \rho_{H2O} \tag{38}
\]

Where:

- \( m_{PJ,i,j,y} \) = Annual chilled/hot water consumption (in mass) of project building unit \( j \) in building unit category \( i \) in year \( y \) (kg/yr)
- \( v_{PJ,i,j,y} \) = Annual chilled/hot water consumption (in volume) of project building unit \( j \) in building unit category \( i \) in year \( y \) (m\(^3\)/yr)
- \( \rho_{H2O} \) = Density of the chilled/hot water (kg/m\(^3\))

The emission factor for chilled/hot water production (\( EF_{PJ,WP,i,j,y} \)) shall be calculated for each centralised chilled/hot water system \( l \) that supplies the chilled/hot water to the respective building unit \( j \) in building unit category \( i \) in year \( y \), according to the following equation. If the supply of chilled/hot water is claimed for CERs in any other registered CDM project, \( EF_{PJ,WP,i,j,y} \) shall be equal to the baseline emission factor of the chilled/hot water supply calculated according to the methodology applied to the registered CDM project. Such treatment is necessary to avoid double counting of emission reductions.

\[
EF_{PJ,WP,i,j,y} = \frac{PE_{WP,EC,Ly} + PE_{WP,FC,Ly} + PE_{WP,FE,Ly}}{WP_{PJ,Ly}} \tag{39}
\]
Where:

\[ \text{EF}_{\text{PJ,WP},j,i,y} = \text{Emission factor for production of chilled/hot water that is supplied to project building unit } j \text{ in building unit category } i \text{ in year } y \ (\text{t CO}_2/\text{GJ}) \]

\[ \text{PE}_{\text{WP,EC},l,y} = \text{Project emissions from electricity consumption of chilled/hot water system } l \text{ in year } y \ (\text{t CO}_2/\text{yr}) \]

\[ \text{PE}_{\text{WP,FC},l,y} = \text{Project emissions from fuel consumption of chilled/hot water system } l \text{ in year } y \ (\text{t CO}_2/\text{yr}) \]

\[ \text{PE}_{\text{WP,FE},l,y} = \text{Project fugitive emissions of CO}_2 \text{ and methane due to release of non-condensable gases from geothermal sources in chilled/hot water production in chilled/hot water system } l \text{ in year } y \ (\text{t CO}_2/\text{yr}) \]

\[ \text{WP}_{\text{PJ},l,y} = \text{Energy content of annual chilled/hot water production of chilled/hot water system } l \text{ in year } y \ (\text{GJ/yr}) \]

If a heat meter(s) is installed for monitoring of the chilled/hot water production in the chilled/hot water system \( l \), \( \text{WP}_{\text{PJ},l,y} \) can be derived directly from the meter reading. If only a mass or volume flow meter(s) is installed, \( \text{WP}_{\text{PJ},l,y} \) is calculated according to the following equations:

\[ \text{WP}_{\text{PJ},l,y} = m_{\text{PJ},l,y} \times \Delta t_{\text{PJ},l,y} \times C_m \]  \hspace{1cm} (40)

Where:

\[ \text{WP}_{\text{PJ},l,y} = \text{Energy content of annual chilled/hot water production of chilled/hot water system } l \text{ in year } y \ (\text{GJ/yr}) \]

\[ m_{\text{PJ},l,y} = \text{Annual chilled/hot water production (in mass) of chilled/hot water system } l \text{ in year } y \ (\text{kg/yr}) \]

\[ \Delta t_{\text{PJ},l,y} = \text{Average temperature difference between the outlet and inlet of the heat exchanger used for the chilled/hot water production in chilled/hot water system } l \text{ in year } y \ (\text{K}) \]

\[ C_m = \text{Specific heat capacity of the chilled/hot water (GJ/(kg·K))} \]

In case a volumetric flow meter, and not a mass flow meter, is installed, \( m_{\text{PJ},l,y} \) is calculated using the following equation:

\[ m_{\text{PJ},l,y} = v_{\text{PJ},l,y} \times \rho_{\text{H}_2\text{O}} \]  \hspace{1cm} (41)

Where:

\[ m_{\text{PJ},l,y} = \text{Annual chilled/hot water production (in mass) of chilled water system } l \text{ in year } y \ (\text{kg/yr}) \]

\[ v_{\text{PJ},l,y} = \text{Annual chilled/hot water production (in volume) of chilled water system } l \text{ in year } y \ (\text{m}^3/\text{yr}) \]

\[ \rho_{\text{H}_2\text{O}} = \text{Density of the chilled water (kg/m}^3\text{)} \]

The project emissions from electricity consumption of chilled/hot water system \( l \) in year \( y \) \( (\text{PE}_{\text{WP,EC},l,y}) \) shall be calculated using the latest approved version of the “Tool to calculate baseline, project and/or leakage emissions from electricity consumption”. The electricity consumption includes the consumption all electrical equipment as a part of central chilled/ hot water system e.g. compressor, pumps etc.

The project emissions from fossil fuel consumption of chilled/hot water system \( l \) in year \( y \) \( (\text{PE}_{\text{WP,FC},l,y}) \) shall be calculated using the latest approved version of the “Tool to calculate project or leakage CO_2 emissions from fossil fuel combustion”.

29/96
In case all or part of the heat consumed in chilled/hot water system \(l\) is supplied by a geothermal source, the fugitive emissions from these sources are calculated as follows:

\[
PE_{WP,FE,ly} = (w_{\text{PJ,steam,CO2,ly}} + w_{\text{PJ,steam,CH4,ly}} \times GWP_{\text{CH4,ly}}) \times M_{\text{PJ,steam,ly}}
\]  

(42)

Where:

- \(PE_{WP,FE,ly}\) = Project fugitive emissions of \(\text{CO}_2\) and methane due to release of non-condensable gases from geothermal sources in chilled/hot water production in chilled/hot water system \(l\) in year \(y\) (t \(\text{CO}_2/\text{yr}\))
- \(w_{\text{PJ,steam,CO2,ly}}\) = Average mass fractions of \(\text{CO}_2\) in the produced steam for the use in chilled/hot water system \(l\) in year \(y\) (t \(\text{CO}_2/\text{t steam}\))
- \(w_{\text{PJ,steam,CH4,ly}}\) = Average mass fractions of methane in the produced geothermal steam for the use in chilled/hot water system \(l\) in year \(y\) (t \(\text{CH}_4/\text{t steam}\))
- \(GWP_{\text{CH4}}\) = Global Warming Potential of methane valid for the relevant commitment period (t \(\text{CO}_2e/\text{tCH}_4\))
- \(M_{\text{PJ,steam,ly}}\) = Quantity of geothermal steam produced for the use in chilled/hot water system \(l\) in year \(y\) (t/yr)

**Sub-step 3.4: Calculation of project emissions from the use of a refrigerant(s) (\(PE_{\text{ref},ij,y}\))**

The project emissions from the use of a refrigerant(s) in project building unit \(j\) in building unit category \(i\) in year \(y\) (\(PE_{\text{ref},ij,y}\)) shall be calculated as follows:

\[
PE_{\text{ref},ij,y} = \sum_m\left(Q_{\text{PJ,ref},ij,m,y} + Q_{\text{PJ,ref},ij,m,\text{Start},y} - Q_{\text{PJ,ref},ij,m,\text{End},y}\right) \times GWP_{\text{PJ,ref},ij,m,y} + PE_{WP,ref,ly} \times \frac{WC_{\text{PJ},ij,y}}{WC_{\text{PJ},ij,y}} \times WP_{\text{PJ},ly}
\]  

(43)

Where:

- \(PE_{\text{ref},ij,y}\) = Project emissions from the use of a refrigerant(s) in project building unit \(j\) in building unit category \(i\) in year \(y\) (t \(\text{CO}_2e/\text{yr}\))
- \(Q_{\text{PJ,ref},ij,m,y}\) = Annual quantity of refrigerant type \(m\) used to replace the refrigerant(s) that has leaked in project building unit \(j\) in building unit category \(i\) in year \(y\), excluding refrigerant leakage from chilled water system (t refrigerant/yr)
- \(Q_{\text{PJ,ref},ij,m,\text{Start},y}\) = Quantity of the initial charge of refrigerant type \(m\) in chiller(s) used in project building unit \(j\) in building unit category \(i\) in year \(y\), excluding refrigerant leakage from chilled water system (t refrigerant/yr)
- \(Q_{\text{PJ,ref},ij,m,\text{End},y}\) = Quantity of refrigerant type \(m\) in chiller(s) used in project building unit \(j\) in building unit category \(i\) that is recovered and destroyed or re-used in year \(y\), excluding refrigerant leakage from chilled water system (t refrigerant/yr)
- \(GWP_{\text{PJ,ref},ij,m,y}\) = Global Warming Potential of refrigerant type \(m\) used in project building unit \(j\) in building unit category \(i\) in year \(y\) (t \(\text{CO}_2e/\text{t refrigerant}\))
- \(WC_{\text{PJ},ij,y}\) = Energy content of annual chilled water consumption in project building unit \(j\) in building unit category \(i\) in year \(y\) (GJ/yr)
PE_{WP,ref,l,y} = Project emissions from the use of a refrigerant in chilled water system \( l \) in year \( y \) (t CO\(_2\)/yr)

\( \eta_{PJ,\text{dist},l,y} \) Average technical distribution losses of the chilled/hot water system \( l \) in year \( y \) (GJ of technical thermal energy losses in the chilled/hot water distribution network divided by GJ of thermal energy supplied to the building units)

WP_{PJ,l,y} = Energy content of annual chilled/hot water production of chilled/hot water system \( l \) in year \( y \) (GJ/yr)

The project emissions from the use of a refrigerant in chilled/hot water system \( l \) in year \( y \) (PE_{WP,ref,l,y}) are calculated as follows:

\[
PE_{WP,ref,l,y} = \left( Q_{PJ,ref,l,y} + Q_{PJ,ref,l,\text{Start},y} - Q_{PJ,ref,l,\text{End},y} \right) \times GWP_{PJ,ref,l,y}
\]  

Where:

- **PE_{WP,ref,l,y}** = Project emissions from the use of a refrigerant in chilled water system \( l \) in year \( y \) (t CO\(_2\)/yr)
- **Q_{PJ,ref,l,y}** = Average annual quantity of the refrigerant used to replace the refrigerant that has leaked in chilled water system \( l \) in year \( y \) (t refrigerant/yr)
- **Q_{PJ,ref,l,\text{Start},y}** = Quantity of the initial charge of the refrigerant in chilled water system \( l \) in year \( y \) (t refrigerant/yr)
- **Q_{PJ,ref,l,\text{End},y}** = Quantity of the refrigerant in chilled water system \( l \) that is recovered and destroyed or re-used in year \( y \) (t refrigerant/yr)
- **GWP_{PJ,ref,l,y}** = Global Warming Potential of the refrigerant used in chilled water system \( l \) in year \( y \) (t CO\(_2\)e/t refrigerant)

**Step 4: Calculation of project emissions**

**Sub-step 4.a:** Follow this step if fuel switching measures of the project activity are demonstrated additional or separate additionality demonstration of the fuel switching measures is not required

If all the building units in the project boundary are monitored as project building units, the project emission shall be calculated as follows:

\[
PE_y = \sum_i \sum_j PE_{i,j,y} \times \text{DISC}_{i,y}
\]  

Where:

- **PE\(_y\)** = Project emissions from project building units in year \( y \) (t CO\(_2\)e/yr)
- **PE\(_{i,j,y}\)** = Project emissions from project building unit \( j \) in building unit category \( i \) in year \( y \) (t CO\(_2\)e/yr)
- **DISC\(_{i,y}\)** = Discount factor for double-counting of emissions reductions due to overlapping use of efficient appliances in building unit category \( i \) in year \( y \). The discount factor is to be calculated using equation provided in the section on baseline emissions
If a sample of building units in the project boundary is monitored as project building units, calculate the SE of project building unit \( j \) in building unit category \( i \) in year \( y \), defined as emissions per GFA in square metre per year:

\[
\text{SE}_{\text{PJ},i,j,y} = \frac{\text{PE}_{i,j,y}}{\text{GFA}_{\text{PJ},i,j,y}}
\]

(46)

Where:
- \( \text{SE}_{\text{PJ},i,j,y} \) = Specific emissions of project building unit \( j \) in building unit category \( i \) in year \( y \), defined as emissions per GFA in square metre per year (t CO\(_2\)e/(m\(^2\)·yr))
- \( \text{PE}_{i,j,y} \) = Project emissions of project building unit \( j \) in building unit category \( i \) in year \( y \) (t CO\(_2\)e/yr)
- \( \text{GFA}_{\text{PJ},i,j,y} \) = GFA of project building unit \( j \) in building unit category \( i \) in year \( y \) (m\(^2\))

Then, calculate the average SE of the project building units in building unit category \( i \) in year \( y \) (\( \mu_{\text{SE},\text{PJ},i,y} \)), adjusting for the sample error as follows:

\[
\text{SE}_{\text{PJ},i,y} = \mu_{\text{SE},\text{PJ},i,y} + t_{0.05} \times \frac{\sigma_{\text{SE},\text{PJ},i,y}}{\sqrt{n_{\text{PJ},i,y}}}
\]

(47)

Where:
- \( \text{SE}_{\text{PJ},i,y} \) = Mean of specific emissions of project building units in building unit category \( i \) in year \( y \), defined as emissions per GFA in square meter per year (t CO\(_2\)e/(m\(^2\)·yr))
- \( \mu_{\text{SE},\text{PJ},i,y} \) = Sample mean of specific emissions of project building units in building unit category \( i \) in year \( y \) (t CO\(_2\)e/(m\(^2\)·yr))
- \( t_{0.05} \) = t-value for a 90% statistical significance level (1.645)
- \( \sigma_{\text{SE},\text{PJ},i,y} \) = Standard deviation of specific emissions of project building units in building unit category \( i \) in year \( y \) (t CO\(_2\)e/(m\(^2\)·yr))
- \( n_{\text{PJ},i,y} \) = Total number of project building units included in the sample for building unit category \( i \) in year \( y \)

\[
\mu_{\text{SE},\text{PJ},i,y} = \frac{\sum_{j} \text{SE}_{\text{PJ},i,j,y}}{n_{\text{PJ},i,y}}
\]

(48)

Where:
- \( \mu_{\text{SE},\text{PJ},i,y} \) = Sample mean of specific emissions of project building units in building unit category \( i \) in year \( y \) (t CO\(_2\)e/(m\(^2\)·yr))
- \( \text{SE}_{\text{PJ},i,j,y} \) = Specific emissions of project building unit \( j \) in building unit category \( i \) in year \( y \), defined as emissions per GFA in square meter per year (t CO\(_2\)e/(m\(^2\)·yr))
- \( n_{\text{PJ},i,y} \) = Total number of project building units included in the sample for building unit category \( i \) in year \( y \)
\[ \sigma_{SE,PJ,i,y} = \sqrt{\frac{\sum_{j} (SE_{PJ,i,j,y} - \mu_{SE,PJ,i,y})^2}{n_{PJ,i,y} - 1}} \] (49)

Where:
- \( \sigma_{SE,PJ,i,y} \) = Standard deviation of specific emissions of project building units in building unit category \( i \) in year \( y \) (t CO\(_2\)/m\(^2\)-yr)
- \( SE_{PJ,i,j,y} \) = Specific emissions of project building unit \( j \) in building unit category \( i \) in year \( y \), defined as emissions per GFA in square metre per year (t CO\(_2\)/m\(^2\)-yr)
- \( \mu_{SE,PJ,i,y} \) = Sample mean of specific emissions of project building units in building unit category \( i \) in year \( y \) (t CO\(_2\)/m\(^2\)-yr)
- \( n_{PJ,i,y} \) = Total number of project building units included in the sample for building unit category \( i \) in year \( y \)

Based on \( SE_{PJ,i,y} \) determined above, the project emissions are calculated by multiplying \( SE_{PJ,i,y} \) by the total GFA of the project building units in the corresponding building unit category \( i \). Accordingly, the total project emissions are calculated as follows:

\[ PE_y = \sum_{i} SE_{PJ,i,y} \times GFA_{PJ,i,y} \times CF_{PJ,i,y} \] (50)

Where:
- \( PE_y \) = Project emissions of project building units in year \( y \) (t CO\(_2\)/yr)
- \( SE_{PJ,i,y} \) = Mean of specific emissions of project building units in building unit category \( i \) in year \( y \), defined as emissions per GFA in square metre per year (t CO\(_2\)/m\(^2\)-yr)
- \( GFA_{PJ,i,y} \) = Total GFA of project building units in building unit category \( i \) in year \( y \) (m\(^2\))
- \( CF_{PJ,i,y} \) = Correction factor for occupancy of project building units in building unit category \( i \) in year \( y \)

The project correction factor for occupancy of project building units (\( CF_{PJ,i,y} \)) is set to one if all the building units in the project boundary are monitored as project building units. If a sample of building units in the project boundary is monitored as project building units, \( CF_{PJ,i,y} \) shall be calculated as follows:

\[ CF_{PJ,i,y} = 1 - \left( \frac{\lambda_{PJ,i,y} - t_{0.05} \times \sqrt{\frac{\lambda_{PJ,i,y} \times (1 - \lambda_{PJ,i,y})}{n_{PJ,i,y}}}}{n_{PJ,i,y}} \right) \] (51)

Where:
- \( CF_{PJ,i,y} \) = Project correction factor for occupancy of project building units in building unit category \( i \) in year \( y \)
- \( \lambda_{PJ,i,y} \) = Share of building units not meeting the occupancy criterion for project building units in building unit category \( i \) in year \( y \)
- \( t_{0.05} \) = t-value for a 90% statistical significance level (1.645)
- \( n_{PJ,i,y} \) = Total number of project building units included in the sample for building unit category \( i \) in year \( y \)
Sub-step 4.b: Follow this step if fuel switching measures of the project activity are not demonstrated additional or the project activity does not claim CERs for emission reductions from the fuel switching measures

The project emissions shall be calculated as follows:

\[
PE_y = \sum_i \left\{ \left[ \frac{ECI_{PJ,i,y} \times CI_{Top20%,EC,i,y} + FCI_{PJ,i,k,y} \times CI_{Top20%,FC,i,y}}{WCI_{PJ,i,y} \times CI_{Top20%,WC,i,y} + REFI_{PJ,i,y}} \right] \times GFA_{PJ,i,y} \times CF_{PJ,i,y} \times DISC_{i,y} \right\}
\]

Where:

- \( PE_y \) = Project emissions from project building units in year \( y \) (t CO\(_2\)e/yr)
- \( ECI_{PJ,i,y} \) = Average specific electricity consumption of project building units in building unit category \( i \) in year \( y \) (MWh/(m\(^2\)·yr))
- \( CI_{Top20%,EC,i,y} \) = Average carbon intensity of electricity used in the top 20% performer baseline building units in building unit category \( i \) in year \( y \) (t CO\(_2\)e/MWh)
- \( FCI_{PJ,i,k,y} \) = Average specific consumption of energy of fossil fuel type \( k \) of project building units in building unit category \( i \) in year \( y \) (MWh/(m\(^2\)·yr))
- \( CI_{Top20%,FC,i,y} \) = Average carbon intensity of fossil fuel used in the top 20% performer baseline building units in building unit category \( i \) in year \( y \) (t CO\(_2\)e/MWh)
- \( WCI_{PJ,i,y} \) = Average specific chilled/hot water consumption of project building units in building unit category \( i \) in year \( y \) (GJ/(m\(^2\)·yr))
- \( CI_{Top20%,WC,i,y} \) = Average carbon intensity of chilled/hot water used in the top 20% performer baseline building units in building unit category \( i \) in year \( y \) (t CO\(_2\)e/GJ)
- \( REFI_{PJ,i,y} \) = Average specific emissions from the use of a refrigerant(s) in project building units in building unit category \( i \) in year \( y \) (t CO\(_2\)e/(m\(^2\)·yr))
- \( GFA_{PJ,i,y} \) = Total GFA of project building units in building unit category \( i \) in year \( y \) (m\(^2\))
- \( CF_{PJ,i,y} \) = Project correction factor for occupancy of project building units in building unit category \( i \) in year \( y \), calculated applying the equations (51) and (52)
- \( DISC_{i,y} \) = Discount factor for double-counting of emissions reductions due to overlapping use of efficient appliances in building unit category \( i \) in year \( y \). The discount factor is to be calculated using equation provided in the section on baseline emissions.

\[\lambda_{PJ,i,y} = \frac{n_{PJ,UNO,i,y}}{n_{PJ,i,y}} \] (52)

Where:

- \( \lambda_{PJ,i,y} \) = Share of building units not meeting the occupancy criterion for project building units in building unit category \( i \) in year \( y \)
- \( n_{PJ,UNO,i,y} \) = Total number of project building units not satisfying the occupancy criterion in the sample for building unit category \( i \) in year \( y \). See Step 2 “Identification of project building units” for the occupancy criterion
- \( n_{PJ,i,y} \) = Total number of project building units included in the sample for building unit category \( i \) in year \( y \)

\[\eta_i, PJ, \gamma_i, UNO, PJ, \gamma_i, n = \lambda_{PJ,i,y} \] (53)

30 In this equation, the carbon intensity of energy sources is derived from the parameters used for the baseline emission calculation in order to exclude emission reductions from fuel switching measures.
**Calculation of average carbon intensity of energy sources**

Using the same set of top 20% performer building units identified in sub-step 4.1 of the baseline emission calculation, the average carbon intensity of different energy sources ($\text{CI}_{\text{Top20\%},\text{EC},i,y}$, $\text{CI}_{\text{Top20\%},\text{FC},i,y}$ and $\text{CI}_{\text{Top20\%},\text{WC},i,y}$) shall be calculated.

The average carbon intensity of electricity used in the top 20% performer building units ($\text{CI}_{\text{Top20\%},\text{EC},i,y}$) is calculated as follows:

$$
\text{CI}_{\text{Top20\%},\text{EC},i,y} = \frac{\sum_{j} \text{CI}_{\text{Top20\%},\text{EC},i,j,y}}{J_{i,y}}
$$

(54)

Where:
- $\text{CI}_{\text{Top20\%},\text{EC},i,y}$ = Average carbon intensity of electricity used in the top 20% performer building units in building unit category $i$ in year $y$ (t CO$_2$/MWh)
- $\text{CI}_{\text{Top20\%},\text{EC},i,j,y}$ = Carbon intensity of electricity used in top 20% performer baseline building unit $j$ in building unit category $i$ in year $y$ (t CO$_2$/MWh)
- $J_{i,y}$ = Total number of top 20% performer baseline building units in building unit category $i$ in year $y$. It is calculated as the product of the number of baseline building units monitored in building category $i$ and 20%, rounded down to the next integer if it is decimal

$\text{CI}_{\text{Top20\%},\text{EC},i,j,y}$ is the carbon intensity of electricity used in baseline building unit $j$ in building unit category $i$ in year $y$ ($\text{CI}_{\text{BL},\text{EC},i,j,y}$), which is calculated as follows:

$$
\text{CI}_{\text{BL},\text{EC},i,j,y} = \frac{\text{BE}_{\text{EC},i,j,y}}{\text{EC}_{\text{BL},i,j,y}}
$$

(55)

Where:
- $\text{CI}_{\text{BL},\text{EC},i,j,y}$ = Carbon intensity of electricity used in baseline building unit $j$ in building unit category $i$ in year $y$ (t CO$_2$/MWh)
- $\text{BE}_{\text{EC},i,j,y}$ = Baseline emissions from electricity consumption of baseline building unit $j$ in building unit category $i$ in year $y$ (t CO$_2$/yr)
- $\text{EC}_{\text{BL},i,j,y}$ = Electricity consumption of baseline building unit $j$ in building unit category $i$ in year $y$ (MWh/yr)

The average carbon intensity of fuel used in the top 20% performer building units ($\text{CI}_{\text{Top20\%},\text{FC},i,y}$) is calculated as follows:

$$
\text{CI}_{\text{Top20\%},\text{FC},i,y} = \frac{\sum_{j} \text{CI}_{\text{Top20\%},\text{FC},i,j,y}}{J_{i,y}}
$$

(56)
Where:
\[ \text{CI}_{\text{Top20\%,FC},i,j,y} = \text{Average carbon intensity of fuel used in the top 20\% performer baseline building units in building unit category } i \text{ in year } y \text{ (t CO}_2\text{e/MWh)} \]
\[ \text{CI}_{\text{Top20\%,FC},i,j,y} = \text{Carbon intensity of fuel used in top 20\% performer baseline building unit } j \text{ in building unit category } i \text{ in year } y \text{ (t CO}_2\text{e/MWh)} \]
\[ J_{i,y} = \text{Total number of top 20\% performer baseline building units in building unit category } i \text{ in year } y \text{ (t CO}_2\text{e/yr). It is calculated as the product of the number of baseline building units monitored in building category } i \text{ and 20\%, rounded down to the next integer if it is decimal} \]

\[ \text{CI}_{\text{Top20\%,FC},i,j,y} \text{ is the carbon intensity of fuel used in baseline building unit } j \text{ in building unit category } i \text{ in year } y \text{ (CI}_{\text{BL,FC},i,j,y}), \text{ which is calculated as follows:} \]
\[ \text{CI}_{\text{BL,FC},i,j,y} = \frac{\text{BE}_{\text{FC},i,j,y}}{\text{FC}_{\text{BL},i,j,y}} \] (57)

Where:
\[ \text{CI}_{\text{BL,FC},i,j,y} = \text{Carbon intensity of fuel used in baseline building unit } j \text{ in building unit category } i \text{ in year } y \text{ (t CO}_2\text{e/MWh)} \]
\[ \text{BE}_{\text{FC},i,j,y} = \text{Baseline emissions from fuel consumption of baseline building unit } j \text{ in building unit category } i \text{ in year } y \text{ (t CO}_2\text{e/yr)} \]
\[ \text{FC}_{\text{BL},i,j,y} = \text{Fuel consumption of baseline building unit } j \text{ in building unit category } i \text{ in year } y \text{ (MWh/yr)} \]

The average carbon intensity of chilled/hot water used in the top 20\% performer building units (\[ \text{CI}_{\text{Top20\%,WC},i,y} \]) is calculated as follows:
\[ \text{CI}_{\text{Top20\%,WC},i,y} = \frac{\sum_{j=1}^{J_{i,y}} \text{CI}_{\text{Top20\%,WC},i,j,y}}{J_{i,y}} \] (58)

Where:
\[ \text{CI}_{\text{Top20\%,WC},i,y} = \text{Average carbon intensity of chilled/hot water used in the top 20\% performer building units in building unit category } i \text{ in year } y \text{ (t CO}_2\text{e/GJ)} \]
\[ \text{CI}_{\text{Top20\%,WC},i,j,y} = \text{Carbon intensity of chilled/hot water used in top 20\% performer baseline building unit } j \text{ in building unit category } i \text{ in year } y \text{ (t CO}_2\text{e/GJ)} \]
\[ J_{i,y} = \text{Total number of top 20\% performer building units in baseline building unit category } i \text{ in year } y \text{ (t CO}_2\text{e/yr). It is calculated as the product of the number of baseline building units monitored in building category } i \text{ and 20\%, rounded down to the next integer if it is decimal} \]

\[ \text{CI}_{\text{Top20\%,WC},i,j,y} \text{ is a subset of carbon intensity of chilled/hot water used in baseline building unit } j \text{ in building unit category } i \text{ in year } y \text{ (CI}_{\text{BL,WC},i,j,y}), \text{ which is calculated as follows:} \]
\[ \text{CI}_{\text{BL,WC},i,j,y} = \frac{\text{BE}_{\text{WC},i,j,y}}{\text{WC}_{\text{BL},i,j,y}} \] (59)
Where:

\[ \text{CI}_{\text{BL,WC},i,j,y} = \text{Carbon intensity of chilled/hot water used in baseline building unit } j \text{ in building unit category } i \text{ in year } y \text{ (t CO}_2\text{e/GJ)} \]

\[ \text{BE}_{WC,i,j,y} = \text{Baseline emissions from chilled/hot water consumption of baseline building unit } j \text{ in building unit category } i \text{ in year } y \text{ (t CO}_2\text{e/yr)} \]

\[ \text{WC}_{BL,i,j,y} = \text{Energy content of annual chilled/hot water consumption in baseline building unit } j \text{ in building unit category } i \text{ in year } y \text{ (GJ/yr)} \]

If a sample of building units in the project boundary is monitored as baseline building units, the calculated \( \text{CI}_{\text{Top20%},EC,i,y}, \text{CI}_{\text{Top20%},FC,i,y} \) and \( \text{CI}_{\text{Top20%},WC,i,y} \) shall be conservatively adjusted for the sampling error. Namely, the adjustment requires \( \text{CI}_{\text{Top20%},EC,i,y}, \text{CI}_{\text{Top20%},FC,i,y} \) and \( \text{CI}_{\text{Top20%},WC,i,y} \) to be the higher-bound value of the confidence interval established around the average CI of electricity, fuel and chilled/hot water of the top 20% performer building units at a 90% significance level. This sample error adjustment is performed by a bootstrap method. First, create resamples of \( \text{CI}_{\text{BL,EC},i,j,y}, \text{CI}_{\text{Top20%},FC,i,j,y} \) and \( \text{CI}_{\text{BL,WC},i,j,y} \) by repeatedly sampling at random and with replacement from the original sample of \( \text{CI}_{\text{BL,EC},i,j,y} \) and \( \text{CI}_{\text{BL,WC},i,j,y} \). Each resample is the same size as the original sample and the minimum size of the resamples is 1,000. Second, create bootstrap distributions calculating \( \text{CI}_{\text{Top20%},EC,i,y}, \text{CI}_{\text{Top20%},FC,i,y} \) and \( \text{CI}_{\text{Top20%},WC,i,y} \) for each resample according to the equations above. Lastly, the sample-error-adjusted \( \text{CI}_{\text{Top20%},EC,i,y}, \text{CI}_{\text{Top20%},FC,i,y} \) and \( \text{CI}_{\text{Top20%},WC,i,y} \) are the values of \( \text{CI}_{\text{Top20%},EC,i,y}, \text{CI}_{\text{Top20%},FC,i,y} \) and \( \text{CI}_{\text{Top20%},WC,i,y} \) at the 5th percentile of the corresponding bootstrap distribution.

**Calculation of average specific energy consumption and refrigerant leakage**

If all the building units in the project boundary are monitored as project building units, the average specific electricity consumption of the project building units (\( \text{ECI}_{PJ,i,y} \)) is calculated as follows:

\[
\text{ECI}_{PJ,i,y} = \frac{\sum EC_{PJ,i,j,y}}{N_{PJ,i,y}}
\]

(60)

Where:

\( \text{ECI}_{PJ,i,y} \) = Average specific electricity consumption of project building units in building unit category \( i \) in year \( y \) (MWh/(m\(^2\)·yr))

\( EC_{PJ,i,j,y} \) = Specific electricity consumption of project building unit \( j \) in building unit category \( i \) in year \( y \) (MWh/(m\(^2\)·yr))

\( N_{PJ,i,y} \) = Total number of project building units in the population for building unit category \( i \) in year \( y \)

\[
\text{ECI}_{PJ,i,j,y} = \frac{EC_{PJ,i,j,y}}{GFA_{PJ,i,j,y}}
\]

(61)

---

31 Refer to Hesterberg et al. (2005) for more details of the bootstrap method.
32 Sampling with replacement means that after randomly drawing an observation from the original sample, it is put back before drawing the next observation.
Where:

\( \text{ECI}_{Pj,i,j,y} \) = Specific electricity consumption of project building unit \( j \) in building unit category \( i \) in year \( y \) (MWh/(m\(^2\)·yr))

\( \text{EC}_{Pj,i,j,y} \) = Electricity consumption of baseline building unit \( j \) in building unit category \( i \) in year \( y \) (MWh/yr)

\( \text{GFA}_{Pj,i,j,y} \) = GFA of project building unit \( j \) in building unit category \( i \) in year \( y \) (m\(^2\))

If all the building units in the project boundary are monitored as project building units, the average specific consumption fossil fuel type \( k \) of project building units (FCI\(_{Pj,i,k,y}\)) is calculated as follows:

\[
\text{FCI}_{Pj,i,k,y} = \frac{\sum_j \text{FCI}_{Pj,i,j,k,y}}{N_{Pj,i,y}} \quad (62)
\]

Where:

\( \text{FCI}_{Pj,i,k,y} \) = Average specific consumption of fossil fuel type \( k \) of project building units in building unit category \( i \) in year \( y \) (mass or volume unit/(m\(^2\)·yr))

\( \text{FCI}_{Pj,i,j,k,y} \) = Specific consumption of fossil fuel type \( k \) of project building unit \( j \) in building unit category \( i \) in year \( y \) (mass or volume unit/(m\(^2\)·yr))

\( N_{Pj,i,y} \) = Total number of project building units in the population for building unit category \( i \) in year \( y \)

\[
\text{FCI}_{Pj,i,j,k,y} = \frac{\text{FC}_{Pj,i,j,k,y}}{\text{GFA}_{Pj,i,j,y}} \quad (63)
\]

Where:

\( \text{FCI}_{Pj,i,j,k,y} \) = Specific consumption of fossil fuel type \( k \) of project building unit \( j \) in building unit category \( i \) in year \( y \) (mass or volume unit/(m\(^2\)·yr))

\( \text{FC}_{Pj,i,j,k,y} \) = Annual consumption of fossil fuel type \( k \) of project building unit \( j \) in building unit category \( i \) in year \( y \). The amount of fuel used for the electricity generation by the captive power plant(s) in the building that project building unit \( j \) belongs to shall not be included in the parameter (mass or volume unit/yr)

\( \text{GFA}_{Pj,i,j,y} \) = GFA of project building unit \( j \) in building unit category \( i \) in year \( y \) (m\(^2\))

If all the building units in the project boundary are monitored as project building units, the average specific chilled/hot water consumption of project building units (WCI\(_{Pj,i,y}\)) is calculated as follows:

\[
\text{WCI}_{Pj,i,y} = \frac{\sum_j \text{WCI}_{Pj,i,j,y}}{N_{Pj,i,y}} \quad (64)
\]
Where:

- \( WCI_{PJ,i,y} \) = Average specific chilled/hot water consumption of project building units in building unit category \( i \) in year \( y \) (GJ/(m\(^2\)·yr))
- \( WCI_{PJ,i,j,y} \) = Specific chilled/hot water consumption of project building unit \( j \) in building unit category \( i \) in year \( y \) (GJ/(m\(^2\)·yr))
- \( N_{PJ,i,y} \) = Total number of project building units in the population for building unit category \( i \) in year \( y \)

\[
WCI_{PJ,i,j,y} = \frac{WC_{PJ,i,j,y}}{GFA_{PJ,i,j,y}} \tag{65}
\]

Where:

- \( WC_{PJ,i,j,y} \) = Specific chilled/hot water consumption of project building unit \( j \) in building unit category \( i \) in year \( y \) (GJ/(m\(^2\)·yr))
- \( WC_{PJ,i,j,y} \) = Energy content of annual chilled/hot water consumption in project building unit \( j \) in building unit category \( i \) in year \( y \) (GJ/yr)
- \( GFA_{PJ,i,j,y} \) = GFA of project building unit \( j \) in building unit category \( i \) in year \( y \) (m\(^2\))

If all the building units in the project boundary are monitored as project building units, the average specific emissions from the use of a refrigerant(s) in project building units (\( REFI_{PJ,i,y} \)) is calculated as follows:

\[
REFI_{PJ,i,y} = \frac{\sum_{j} REFI_{PJ,i,j,y}}{N_{PJ,i,y}} \tag{66}
\]

Where:

- \( REFI_{PJ,i,y} \) = Average specific emissions from the use of a refrigerant(s) in project building units in building unit category \( i \) in year \( y \) (t CO\(_2\)e/(m\(^2\)·yr))
- \( REFI_{PJ,i,j,y} \) = Specific emissions from the use of a refrigerant(s) in project building unit \( j \) in building unit category \( i \) in year \( y \) (t CO\(_2\)e/(m\(^2\)·yr))
- \( N_{PJ,i,y} \) = Total number of project building units in the population for building unit category \( i \) in year \( y \)

\[
REFI_{PJ,i,j,y} = \frac{PE_{ref,i,j,y}}{GFA_{PJ,i,j,y}} \tag{67}
\]

Where:

- \( REFI_{PJ,i,j,y} \) = Specific emissions from the use of a refrigerant(s) in project building unit \( j \) in building unit category \( i \) in year \( y \) (t CO\(_2\)e/(m\(^2\)·yr))
- \( PE_{ref,i,j,y} \) = Project emissions from the use of a refrigerant(s) in project building unit \( j \) in building unit category \( i \) in year \( y \) (t CO\(_2\)e/yr)
- \( GFA_{PJ,i,j,y} \) = GFA of project building unit \( j \) in building unit category \( i \) in year \( y \) (m\(^2\))
If a sample of building units in the project boundary is monitored as project building units, the calculated ECI\textsubscript{PJ,i,y}, FCI\textsubscript{PJ,i,k,y}, WCI\textsubscript{PJ,i,y} and REFI\textsubscript{PJ,i,y} shall be conservatively adjusted for the sampling error. Namely, the adjustment requires ECI\textsubscript{PJ,i,y}, FCI\textsubscript{PJ,i,k,y}, WCI\textsubscript{PJ,i,y} and REFI\textsubscript{PJ,i,y} to be the higher-bound value of the confidence interval established around the average EI and REFI of the project building units at a 90% significance level.

\[
\text{ECI}_{PJ,i,y} = \mu_{ECI,PJ,i,y} + t_{0.05} \times \frac{\sigma_{ECI,PJ,i,y}}{\sqrt{n_{PJ,i,y}}} \quad (68)
\]

and

\[
\text{FCI}_{PJ,i,k,y} = \mu_{FCI,PJ,i,k,y} + t_{0.05} \times \frac{\sigma_{FCI,PJ,i,k,y}}{\sqrt{n_{PJ,i,y}}} \quad (69)
\]

and

\[
\text{WCI}_{PJ,i,y} = \mu_{WCI,PJ,i,y} + t_{0.05} \times \frac{\sigma_{WCI,PJ,i,y}}{\sqrt{n_{PJ,i,y}}} \quad (70)
\]

and

CDM – Meth Panel

Forty-ninth meeting
Report
Annex 1
Sectoral scope: 03

REFI$_{PJ,i,j,y}$ = Specific emissions from the use of a refrigerant(s) in project building unit $j$ in building unit category $i$ in year $y$ ($t$ CO$_2$e/($m^2$·yr))

μ$_{ECL,PJ,i,j,y}$ = Sample mean of specific electricity consumption of project building units in building unit category $i$ in year $y$ (MWh/(m$^2$·yr))

μ$_{FCI,PJ,i,j,k,y}$ = Sample mean of specific consumption of fossil fuel type $k$ of project building units in building unit category $i$ in year $y$ (mass or volume unit/(m$^2$·yr))

μ$_{WCI,PJ,i,j,y}$ = Sample mean of specific chilled/hot water consumption of project building units in building unit category $i$ in year $y$ (GJ/(m$^2$·yr))

μ$_{REFI,PJ,i,j,y}$ = Sample mean of specific emissions from the use of a refrigerant(s) in project building units in building unit category $i$ in year $y$ ($t$ CO$_2$e/($m^2$·yr))

n$_{PJ,i,j,y}$ = Total number of project building units included in the sample for building unit category $i$ in year $y$

Step 5: Update of the project emission calculation

In order to reflect the changes in the energy consumption patterns of the project building units over time, the relevant data (EC$_{PJ,i,j,y}$, FC$_{PJ,i,j,k,y}$ and WC$_{PJ,i,j,y}$) shall be collected every year from the same project building units. If a project building unit in a sample group is destroyed or its function is changed, it can be replaced by another building unit with the same function that is randomly sampled.

The calculation of the project emissions from the use of a refrigerant(s) (PE$_{ref,i,j,y}$) shall be updated annually. Alternatively, it can be updated for the first three years of the corresponding crediting period, and for any subsequent year in the crediting period, the maximum annual value of the three-year monitoring period can be used.

All the other project-related data need to be updated every third year (e.g. year 4, 7, 10). The GFA data in the project (GFA$_{PJ,i,j,y}$, GFA$_{PJ-Bldg,i,j,y}$ and GFA$_{PJ,i,y}$) may be updated more frequently in order to reflect the change in the scale of the project activity over time.

Based on the above data, the project emissions shall be updated annually after the project implementation.

All the steps should be documented transparently, including a list of the project building units identified, with information to clearly identify the building units, as well as the relevant data used for the calculation of the project emissions.

Leakage Emissions

In case the project activity involves the replacement of equipment, and the leakage effect of the use of the replaced equipment in another activity is neglected because the replaced equipment is scrapped, an independent monitoring of scrapping of replaced equipment needs to be implemented (SCRAP$_{q,t}$). The monitoring should include a check if the number of project activity equipment distributed by the project and the number of scrapped equipment correspond with each other. For this purpose scrapped equipment should be stored until such correspondence has been checked. The scrapping of replaced equipment should be documented and independently verified.

In case the project activity involves fossil fuel switching measures, leakage resulting from fuel extraction, processing, liquefaction, transportation, re-gasification and distribution of fossil fuels outside of the project boundary shall be considered. The leakage includes mainly fugitive CH$_4$ emissions and CO$_2$ emissions from associated fuel combustion and flaring. In this methodology, the following leakage emission sources shall be considered:
- Fugitive CH$_4$ emissions associated with fuel extraction, processing, of fossil fuels and liquefaction, transportation, re-gasification and distribution of natural gas used in the project plant. In the case LNG is used in the project plant: CO$_2$ emissions from fuel combustion/electricity consumption associated with the liquefaction, transportation, re-gasification and compression into a natural gas transmission or distribution system.

Thus, leakage emissions are calculated as follows:

$$ LE_y = LE_{CH4,y} + LE_{LNG,CO2,y} $$  \(80\)

Where:
- $LE_y$ = Leakage emissions during the year $y$ (t CO$_2$/yr)
- $LE_{CH4,y}$ = Leakage emissions due to fugitive upstream CH$_4$ in the year $y$ (t CO$_2$/yr)
- $LE_{LNG,CO2,y}$ = Leakage emissions due to fossil fuel combustion/electricity consumption associated with the liquefaction, transportation, re-gasification and compression of LNG into a natural gas transmission or distribution system during the year $y$ (t CO$_2$/yr)

Note that to the extent that upstream emissions occur in Annex I countries that have ratified the Kyoto Protocol, from 1 January 2008 onwards, these emissions should be excluded, if technically possible, in the leakage calculations.

**Fugitive methane emissions**

For the purpose of determining fugitive methane emissions associated with the production, and in case of natural gas, the transportation and distribution of the fuels, project participants should multiply the quantity of fossil fuels $k$ consumed in all element processes $i$ with a methane emission factor for these upstream emissions ($EF_{k,upstream,CH4}$), and subtract for all fuel types $k$ which would be used in the absence of the project activity the fuel quantities multiplied with respective methane emission factors ($EF_{k,upstream,CH4}$), as follows:

$$ LE_{CH4,y} = \left[ \sum_k FF_{PJ,k,y} \times NCV_{k,y} \times EF_{k,upstream,CH4} - \sum_k FF_{BL,k,y} \times NCV_{k,y} \times EF_{k,upstream,CH4} \right] \times GWP_{CH4} $$  \(81\)

Where:
- $LE_{CH4,y}$ = Leakage emissions due to fugitive upstream CH$_4$ in the year $y$ (t CO$_2$/yr)
- $FF_{PJ,k,y}$ = Consumption of fossil fuel in all project building units in year $y$ (m$^3$/yr)
- $NCV_{k,y}$ = Average net calorific value of the fuel type $k$ consumed in year $y$ (GJ/m$^3$)
- $EF_{k,upstream,CH4}$ = Emission factor for upstream fugitive methane emissions from production, transportation and distribution of fuel type $k$ (t CH$_4$/GJ fuel supplied to final consumers)
- $FF_{BL,k,y}$ = Consumption of fossil fuel type $k$ (a coal or petroleum fuel type) in all baseline building units in year $y$ (volume or mass unit/yr)
- $NCV_{k,y}$ = Average net calorific value of fossil fuel type $k$ used in year $y$ (GJ/volume or mass unit)
- $EF_{k,upstream,CH4}$ = Emission factor for upstream fugitive methane emissions from production of the fuel type $k$ (a coal or petroleum fuel type) (t CH$_4$/GJ fuel produced)
- $GWP_{CH4}$ = Global Warming Potential of methane valid for the relevant commitment period
Determination of fossil fuel consumption in project building units

If all the building units in the project boundary are monitored as project building units, the total natural gas consumption \( (\text{FF}_{\text{PJ},k,y}) \) shall be calculated as follows:

\[
\text{FF}_{\text{PJ},k,y} = \sum_i \sum_j \text{FF}_{\text{PJ},i,j,y}
\]

(82)

Where:
- \( \text{FF}_{\text{PJ},k,y} \) = Consumption of fossil fuel \( k \) in all project building units in year \( y \) \( (\text{m}^3/\text{yr}) \)
- \( \text{FF}_{\text{PJ},i,j,y} \) = Consumption of fossil fuel \( k \) in project building unit \( j \) in building unit category \( i \) in year \( y \) \( (\text{m}^3/\text{yr}) \)

If a sample of building units in the project boundary is monitored as project building units, calculate \( \text{FF}_{\text{PJ},k,y} \) as follows:

\[
\text{FF}_{\text{PJ},k,y} = \sum_i \text{FF}_{\text{PJ},i,j,y} \times N_{\text{PJ},i,y}
\]

(83)

Where:
- \( \text{FF}_{\text{PJ},k,y} \) = Consumption of fossil fuel \( k \) in all project building units in year \( y \) \( (\text{m}^3/\text{yr}) \)
- \( \text{FF}_{\text{PJ},i,j,y} \) = Mean consumption of fossil fuel \( k \) in project building units in building unit category \( i \) in year \( y \) \( (\text{m}^3/\text{yr}) \)
- \( N_{\text{PJ},i,y} \) = Total number of project building units in the population for building unit category \( i \) in year \( y \)

\[
\text{FF}_{\text{PJ},k,i,y} = \mu_{\text{FF},\text{PJ},k,i,y} + t_{0.05} \times \frac{\sigma_{\text{FF},\text{PJ},k,i,y}}{\sqrt{n_{\text{PJ},i,y}}}
\]

(84)

Where:
- \( \text{FF}_{\text{PJ},k,i,y} \) = Mean consumption of fossil fuel \( k \) in project building units in building unit category \( i \) in year \( y \) \( (\text{m}^3/\text{yr}) \)
- \( \mu_{\text{FF},\text{PJ},k,i,y} \) = Sample mean consumption of fossil fuel \( k \) in project building units in building unit category \( i \) in year \( y \) \( (\text{m}^3/\text{yr}) \)
- \( t_{0.05} \) = \( t \)-value for a 90% statistical significance level (1.645)
- \( \sigma_{\text{FF},\text{PJ},k,i,y} \) = Standard deviation of consumption of fossil fuel \( k \) in project building units in building unit category \( i \) in year \( y \) \( (\text{m}^3/\text{yr}) \)
- \( n_{\text{PJ},i,y} \) = Total number of project building units included in the sample for building unit category \( i \) in year \( y \)

\[
\mu_{\text{FF},\text{PJ},k,i,y} = \frac{\sum_j \text{FF}_{\text{PJ},i,j,y}}{n_{\text{PJ},i,y}}
\]

(85)
Where:

\[ \mu_{FF,PJ,k,i,y} = \text{Sample mean of consumption of fossil fuel } k \text{ in project building units in building unit category } i \text{ in year } y \text{ (m}^3\text{/yr}) \]

\[ FF_{PJ,k,i,y} = \text{Consumption of fossil fuel } k \text{ in project building unit } j \text{ in building unit category } i \text{ in year } y \text{ (m}^3\text{/yr}) \]

\[ n_{PJ,i,y} = \text{Total number of project building units included in the sample for building unit category } i \text{ in year } y \]

\[ \sigma_{FF,PJ,k,i,y} = \sqrt{\frac{\sum_{j} (FF_{PJ,k,i,j,y} - \mu_{FF,PJ,k,i,y})^2}{n_{PJ,i,y} - 1}} \quad (86) \]

Where:

\[ \sigma_{FF,PJ,k,i,y} = \text{Standard deviation of consumption of fossil fuel } k \text{ in project building units in building unit category } i \text{ in year } y \text{ (m}^3\text{/yr}) \]

\[ FF_{PJ,k,i,y} = \text{Consumption of fossil fuel } k \text{ in project building unit } j \text{ in building unit category } i \text{ in year } y \text{ (m}^3\text{/yr}) \]

\[ \mu_{FF,PJ,k,i,y} = \text{Sample mean of consumption of fossil fuel } k \text{ in project building units in building unit category } i \text{ in year } y \text{ (m}^3\text{/yr}) \]

\[ n_{PJ,i,y} = \text{Total number of project building units included in the sample for building unit category } i \text{ in year } y \]

**Determination of fossil fuel consumption in baseline building units**

Consumption of fossil fuel type \( k \) in all baseline building units in year \( y \) (\( FF_{BL,k,y} \)) is calculated as follows:

\[ FF_{BL,k,y} = \sum_i FF_{Top20\%,i,k,y} \times N_{PJ,i,y} \quad (87) \]

Where:

\[ FF_{BL,k,y} = \text{Consumption of fossil fuel type } k \text{ (a coal or petroleum fuel type) in all baseline building units in year } y \text{ (volume or mass unit/yr)} \]

\[ FF_{Top20\%,i,k,y} = \text{Mean consumption of fossil fuel type } k \text{ (a coal or petroleum fuel type) in top 20\% performer building units in building unit category } i \text{ in year } y \text{ (volume or mass unit/yr)} \]

\[ N_{PJ,i,y} = \text{Total number of project building units in the population for building unit category } i \text{ in year } y \]

\[ FF_{Top20\%,i,k,y} = \frac{\sum_j FF_{Top20\%,i,j,k,y}}{J_{i,y}} \quad (88) \]
Where:

\( FF_{\text{Top20%},i,k,y} \) = Mean consumption of fossil fuel type \( k \) (a coal or petroleum fuel type) in top 20% performer building units in building unit category \( i \) in year \( y \) (volume or mass unit/yr)

\( FF_{\text{Top20%},j,i,k,y} \) = Consumption of fossil fuel type \( k \) (a coal or petroleum fuel type) in top 20% performer building unit \( j \) in building unit category \( i \) in year \( y \) (volume or mass unit/yr)

\( J_{j,y} \) = Total number of top 20% performer building units in building unit category \( i \) in year \( y \). It is calculated as the product of the number of baseline building units monitored in building category \( i \) and 20%, rounded down to the next integer if it is decimal.

If sampling of the baseline building units is involved in the calculation of \( FF_{\text{Top20%},i,k,y} \), the calculated \( FF_{\text{Top20%},i,k,y} \) shall be conservatively adjusted for the sampling error. Namely, the adjustment requires \( FF_{\text{Top20%},i,k,y} \) to be the lower-bound value of the confidence interval established around the average consumption of fossil fuel type \( k \) of the top 20% performer building units at a 90% significance level. This sample error adjustment is performed by a bootstrap method.\(^{33} \) First, create resamples of \( FF_{\text{BL},i,j,k,y} \) by repeatedly sampling at random and with replacement\(^{34} \) from the original sample of \( FF_{\text{BL},i,j,k,y} \). Each resample is the same size as the original sample and the minimum size of the resamples is 1,000. Second, create a bootstrap distribution calculating \( FF_{\text{Top20%},i,k,y} \) for each resample according to the equation (88). Lastly, the sample-error-adjusted \( FF_{\text{Top20%},i,k,y} \) is the value of \( FF_{\text{Top20%},i,k,y} \) at the 5% percentile of the bootstrap distribution.

Where reliable and accurate national data on fugitive \( \text{CH}_4 \) emissions associated with the production, and in case of natural gas, the transportation and distribution of the fuels is available, project participants should use this data to determine average emission factors by dividing the total quantity of \( \text{CH}_4 \) emissions by the quantity of fuel produced or supplied respectively.\(^{35} \) Where such data is not available, project participants may use the default values provided in Table 2 below. In this case, the natural gas emission factor for the location of the project should be used, except in cases where it can be shown that the relevant system element (gas production and/or processing/transmission/distribution) is predominantly of recent vintage and built and operated to international standards, in which case the US/Canada values may be used.

Note that the emission factor for fugitive upstream emissions for natural gas (\( EF_{\text{NG,upstream,CH4}} \)) should include fugitive emissions from production, processing, transport and distribution of natural gas, as indicated in the Table 2 below. Note further that in case of coal the emission factor is provided based on a mass unit and needs to be converted in an energy unit, taking into account the net calorific value of the coal.

\(^{33} \) Refer to Hesterberg et al. (2005) for more details of the bootstrap method.

\(^{34} \) Sampling with replacement means that after randomly drawing an observation from the original sample, it is put back before drawing the next observation.

\(^{35} \) GHG inventory data reported to the UNFCCC as part of national communications can be used where country-specific approaches (and not IPCC Tier 1 default values) have been used to estimate emissions.

Note: The emission factors in this table have been derived from IPCC default Tier 1 emission factors provided in Volume 3 of the 1996 Revised IPCC Guidelines, by calculating the average of the provided default emission factor range.

### CO₂ emissions from LNG

Where applicable, CO₂ emissions from fuel combustion/electricity consumption associated with the liquefaction, transportation, re-gasification and compression of LNG into a natural gas transmission or distribution system (LEₙ,LNG,CO₂,y) should be estimated by multiplying the quantity of natural gas combusted in the project with an appropriate emission factor, as follows:

\[
\text{LE}_{\text{LNG,CO}_2,y} = \text{FF}_{\text{PJ},y} \times \text{EF}_{\text{CO}_2,\text{upstream,LNG}}
\]  

(89)

Where:

- \( \text{LE}_{\text{LNG,CO}_2,y} \) = Leakage emissions due to fossil fuel combustion/electricity consumption associated with the liquefaction, transportation, re-gasification and compression of LNG into a natural gas transmission or distribution system in year \( y \) (t CO₂e/yr)
- \( \text{FF}_{\text{PJ},y} \) = Consumption of natural gas in all project building units in year \( y \) (m³/yr)
- \( \text{EF}_{\text{CO}_2,\text{upstream,LNG}} \) = Emission factor for upstream CO₂ emissions due to fossil fuel combustion/electricity consumption associated with the liquefaction, transportation, regasification and compression of LNG into a natural gas transmission or distribution system (t CO₂e/m³)

Where reliable and accurate data on upstream CO₂ emissions due to fossil fuel combustion/electricity consumption associated with the liquefaction, transportation, re-gasification and compression of LNG into a natural gas transmission or distribution system is available, project participants should use this data to
determine an average emission factor. Where such data is not available, project participants may assume a default value of 6 t CO₂/TJ as a rough approximation.\(^{36}\)

**Emission reductions**

Emission reductions are calculated as follows:

\[
ER_y = BE_y - PE_y - LE_y
\]  

(90)

Where:

- \(ER_y\) = Emission reductions in year \(y\) (t CO₂/yr)
- \(BE_y\) = Baseline emissions in year \(y\) (t CO₂/yr)
- \(PE_y\) = Project emissions in year \(y\) (t CO₂/yr)
- \(LE_y\) = Leakage emissions in year \(y\) (t CO₂/yr)

**Changes required for methodology implementation in 2\(^{nd}\) and 3\(^{rd}\) crediting periods**

Refer to the “Tool to assess the validity of the original/current baseline and to update the baseline at the renewal of a crediting period” (Annex 1 of the “Procedures for renewal of the crediting period of a registered CDM project activity”).\(^{37}\)

In applying the aforementioned tool, the following procedure specific to this methodology should be followed. For the parameters monitored \textit{ex post}, there are parameters that require monitoring annually and at least every three years. For the latter parameters, the monitoring frequency does not necessarily coincide with the first year of the 2\(^{nd}\) and the 3\(^{rd}\) crediting periods (i.e., year 8 and 15). Therefore, updating of these parameters is not necessary at the renewal of the crediting period.

**Data and parameters not monitored**

In addition to the parameters listed in the tables below, the provisions on data and parameters not monitored in the tools referred to in this methodology apply.

**Measurement procedures (if any):** -  
**Any comment:** Applicable only if a mass or volume flow meter is installed for monitoring of chilled/hot water consumption

### Data / Parameter: \( \rho_{\text{H2O}} \)

**Data unit:** kg/m³  
**Description:** Density of the chilled/hot water.  
**Measurement procedures (if any):** -  
**Any comment:** Applicable only if a volume flow meter is installed for monitoring of chilled/hot water consumption

### Data / Parameter: \( \text{GWP}_{\text{CH4}} \)

**Data unit:** t CO₂e/t CH₄  
**Description:** Global warming potential of methane valid for the relevant commitment period.  
**Source of data:** The latest version of the IPCC’s assessment report  
**Measurement procedures (if any):** Default value for the first commitment period: 21 t CO₂e/t CH₄.  
**Any comment:** Applicable only if a geothermal source(s) supplies heat to the chilled/hot water cooling system

### Data / Parameter: \( \text{EF}_{\text{NG,upstream,CH4}} \)

**Data unit:** t CH₄/GJ fuel supplied to final consumers  
**Description:** Emission factor for upstream fugitive methane emissions from production, transportation and distribution of natural gas  
**Source of data:** Default values provided in Table 2 “Default emission factor for fugitive CH₄ upstream emissions” in the leakage emissions section  
**Measurement procedures (if any):** -  
**Any comment:** Applicable only if the project activity is implemented under a programme of activities
### Data / Parameter: $\text{EF}_{\text{k,upstream,CH}_4}$

- **Data unit:** t CH$_4$/GJ fuel produced
- **Description:** Emission factor for upstream fugitive methane emissions from production of the fuel type $k$ (a coal or petroleum fuel type)
- **Source of data:** Default values provided in Table 2 “Default emission factor for fugitive CH$_4$ upstream emissions” in the leakage emissions section
- **Measurement procedures (if any):** -
- **Any comment:** Applicable only if the project activity is implemented under a programme of activities

### Data / Parameter: $\text{EF}_{\text{CO}_2,\text{upstream,LNG}}$

- **Data unit:** t CO$_2$/m$^3$
- **Description:** Emission factor for upstream CO$_2$ emissions due to fossil fuel combustion/electricity consumption associated with the liquefaction, transportation, regasification and compression of LNG into a natural gas transmission or distribution system
- **Source of data:** Where reliable and accurate data on upstream CO$_2$ emissions due to fossil fuel combustion/electricity consumption associated with the liquefaction, transportation, re-gasification and compression of LNG into a natural gas transmission or distribution system is available, project participants should use this data to determine an average emission factor. Where such data is not available, project participants may assume a default value of 6 t CO$_2$/TJ as a rough approximation
- **Measurement procedures (if any):** -
- **Any comment:** Applicable only if the project activity is implemented under a programme of activities

### III. MONITORING METHODOLOGY

All data collected as part of monitoring should be archived electronically and be kept at least for 2 years after the end of the last crediting period. 100% of the data should be monitored if not indicated otherwise in the tables below. All measurements should be conducted with calibrated measurement equipment according to relevant industry standards.

In addition, the monitoring provisions in the tools referred to in this methodology apply.

**Data / Parameter:** GFA\(_{BL,i,j,y}\) or GFA\(_{BL-Bldg,i,j,y}\)  
**Data unit:** m\(^2\)  
**Description:**  
- GFA of baseline building unit \(j\) in building unit category \(i\) in year \(y\); or,  
- GFA of the whole building, which baseline building unit \(j\) in building unit category \(i\) belongs to, in year \(y\). Account for GFA of each building unit in the building, but not GFA of the common service areas.  
**Source of data:** The following data sources may be used if the relevant conditions apply:  
<table>
<thead>
<tr>
<th>Data source</th>
<th>Conditions for using the data source</th>
</tr>
</thead>
<tbody>
<tr>
<td>a) Building plan</td>
<td>This is the preferred source</td>
</tr>
<tr>
<td>b) On-site measurement</td>
<td>If a) is not available</td>
</tr>
</tbody>
</table>

**Measurement procedures (if any):** -  
**Monitoring frequency:** For the first year of the project implementation, and every third year thereafter  
**QA/QC procedures:**  
- Confirm on-site that building geometry represented in the plan is accurate;  
- Not applicable  
**Any comment:** GFA\(_{BL-Bldg,i,j,y}\) is applicable only if apportioning of baseline energy consumption and/or baseline emissions related to the use of a refrigerant(s) is required

---

**Data / Parameter:** BE\(_{FC,non-RE_captive,i,j,y}\)  
**Data unit:** t CO\(_2\)/yr  
**Description:** Baseline emissions from electricity consumption of baseline building unit \(j\) in building unit category \(i\) in year \(y\), which is supplied by the grid and/or an off-grid fossil-fuel-fired captive power plant(s).  
**Source of data:** As per the “Tool to calculate baseline, project and/or leakage emissions from electricity consumption”  
**Measurement procedures (if any):** As per the “Tool to calculate baseline, project and/or leakage emissions from electricity consumption”  
**Monitoring frequency:** Annually  
**QA/QC procedures:** As per the “Tool to calculate baseline, project and/or leakage emissions from electricity consumption”  
**Any comment:** -

---

**Data / Parameter:** FC\(_{HL,i,k,y}\) or FC\(_{HL-Bldg,i,j,y}\)  
**Data unit:** Mass or volume unit/yr (e.g. tonne/yr or m\(^3\)/yr)  
**Description:**  
- Annual consumption of fossil fuel type \(k\) of baseline building unit \(j\) in building unit category \(i\) in year \(y\); or,  
- Annual consumption of fossil fuel type \(k\) of the whole building, which baseline building unit \(j\) in building unit category \(i\) belongs to, in year \(y\)  
In both cases, the amount of fuel used for the electricity generation by the captive power plant(s) in the building that baseline building unit \(j\) belongs to shall not be included in the parameter
Source of data: Choose among the following options:
   a) Utility billing records
   b) On-site measurements

Measurement procedures (if any):
   a) As per the utility metering
   b) Use either mass or volume meters

Monitoring frequency:
   a) As per the utility metering
   b) Continuously, aggregated at least annually

QA/QC procedures: Check consistency of the monitored records with the records from previous monitoring intervals

Any comment: FC_{BL-Bldg,i,j,k,Y} is applicable only if the fuel consumption is monitored only at a whole building level

<table>
<thead>
<tr>
<th>Data / Parameter</th>

| Any comment:                  | Applicable only if Option B is used for the calculation of emissions from fossil fuel consumption in a building unit or chilled/hot water system.  
For a): If the fuel supplier does provide the NCV value and the CO_2 emission factor on the invoice and these two values are based on measurements for this specific fuel, this CO_2 factor should be used. If another source for the CO_2 emission factor is used or no CO_2 emission factor is provided, options b), c) or d) should be used |
### Data / Parameter: WC<sub>BL,i,j,y</sub> or WC<sub>BL-Bldg,i,j,y</sub>

**Data unit:** GJ/yr

**Description:**
- Energy content of annual chilled/hot water consumption in baseline building unit <i>j</i> in building unit category <i>i</i> in year <i>y</i>; or,
- Energy content of annual chilled/hot water consumption in the whole building, which baseline building unit <i>j</i> in building unit category <i>i</i> belongs to, in year <i>y</i>

**Source of data:** Choose among the following options:
- Utility billing records
- On-site measurements

**Measurement procedures (if any):**
- As per the utility metering
- Use heat meters

**Monitoring frequency:**
- As per the utility metering
- Continuously, aggregated at least annually

**QA/QC procedures:** Check consistency of the monitored records with the records from previous monitoring intervals

**Any comment:** Applicable only if a heat meter is installed for monitoring of chilled/hot water consumption. WC<sub>BL-Bldg,i,j,k,y</sub> is applicable only if the chilled/hot water consumption is monitored only at a whole building level

### Data / Parameter: η<sub>BL-dist,l,y</sub>

**Data unit:** GJ of technical thermal energy losses in the chilled/hot water distribution network divided by GJ of thermal energy supplied to the building units

**Description:** Average technical distribution losses of the chilled/hot water system <i>l</i> in year <i>y</i>

**Source of data:** Monitoring records of thermal energy supply and demand or thermal energy loss measurement. A default value of 0% may be used if no recent data are available or the data cannot be regarded accurate and reliable

**Measurement procedures (if any):**
- Based on monitoring of thermal energy supply and demand; or
- Measurement and estimation of surface thermal energy losses. Follow authentic engineering handbooks/publications or national or international standards for calculation of the surface thermal energy losses

**Monitoring frequency:** For the first year of the project implementation, and every third year thereafter

**QA/QC procedures:** -

**Any comment:** -
### Data / Parameter: $m_{\text{BL},i,j,y}$

**Data unit:** kg/yr  
**Description:** Annual chilled/hot water consumption (in mass) of baseline building unit $j$ in building unit category $i$ in year $y$.  
**Source of data:** Choose among the following options: 
- a) Utility billing records  
- b) On-site measurements  
**Measurement procedures (if any):** 
- a) As per the utility metering  
- b) Use mass meters  
**Monitoring frequency:** 
- a) As per the utility metering  
- b) Continuously, aggregated at least annually  
**QA/QC procedures:** Check consistency of the monitored records with the records from previous monitoring intervals  
**Any comment:** Applicable only if a mass flow meter is installed for monitoring of chilled/hot water consumption

### Data / Parameter: $v_{\text{BL},i,j,y}$

**Data unit:** m$^3$/yr  
**Description:** Annual chilled/hot water consumption (in volume) of baseline building unit $j$ in building unit category $i$ in year $y$.  
**Source of data:** Choose among the following options: 
- a) Utility billing records  
- b) On-site measurements  
**Measurement procedures (if any):** 
- a) As per the utility metering  
- b) Use volume meters  
**Monitoring frequency:** 
- a) As per the utility metering  
- b) Continuously, aggregated at least annually  
**QA/QC procedures:** Check consistency of the monitored records with the records from previous monitoring intervals  
**Any comment:** Applicable only if a volume flow meter is installed for monitoring of chilled/hot water consumption

### Data / Parameter: $W_{\text{P},i,l,y}$

**Data unit:** GJ/yr  
**Description:** Annual energy content of chilled/hot water production of chilled/hot water system $l$ in year $y$.  
**Source of data:** On-site measurements  
**Measurement procedures (if any):** Use heat meters  
**Monitoring frequency:** For the first year of the project implementation, and every third year thereafter  
**QA/QC procedures:**  
**Any comment:** Applicable only if a heat meter is installed for monitoring of chilled/hot water production

### Data / Parameter: \( w_{BL,\text{steam},CO_2,l,y} \)

| Description: | Average mass fractions of carbon dioxide in the produced steam for the use in chilled/hot water cooling system \( l \) in year \( y \) |
| Source of data: | On-site measurements |

| Measurement procedures (if any): | Non-condensable gases sampling should be carried out in production wells and at the steam field-power plant interface using ASTM Standard Practice E1675 for Sampling 2-Phase Geothermal Fluid for Purposes of Chemical Analysis (as applicable to sampling single phase steam only). The \( CO_2 \) and \( CH_4 \) sampling and analysis procedure consists of collecting non-condensable gases samples from the main steam line with glass flasks, filled with sodium hydroxide solution and additional chemicals to prevent oxidation. Hydrogen sulphide (\( H_2S \)) and carbon dioxide (\( CO_2 \)) dissolve in the solvent while the residual compounds remain in their gaseous phase. The gas portion is then analyzed using gas chromatography to determine the content of the residuals including \( CH_4 \). All alkane concentrations are reported in terms of methane |

| Monitoring frequency: | For the first year of the project implementation, and every third year thereafter |

### Data / Parameter: \( w_{BL,\text{steam},CH_4,l,y} \)

| Description: | Average mass fractions of methane in the produced geothermal steam for the use in chilled/hot water cooling system \( l \) in year \( y \) |
| Source of data: | On-site measurements |

| Measurement procedures (if any): | As per the procedures outlined for \( w_{BL,\text{steam},CO_2,l,y} \). |

| Monitoring frequency: | For the first year of the project implementation, and every third year thereafter |

| QA/QC procedures: | - |

<p>| Any comment: | Applicable only if a geothermal source(s) supplies heat to the chilled/hot water cooling system |</p>

**Description:** Total GFA of project building units in building unit category *i* in year *y*.

**Source of data:** The following data sources may be used if the relevant conditions apply:

<table>
<thead>
<tr>
<th>Data source</th>
<th>Conditions for using the data source</th>
</tr>
</thead>
<tbody>
<tr>
<td>a) Building plan.</td>
<td>This is the preferred source.</td>
</tr>
<tr>
<td>b) On-site measurement.</td>
<td>If a) is not available.</td>
</tr>
</tbody>
</table>

**Measurement procedures (if any):** -

**Monitoring frequency:** For the first year of the project implementation, and every third year thereafter, or more frequently

**QA/QC procedures:**
- a) Confirm on-site that building geometry represented in the plan is accurate
- b) Not applicable

**Any comment:** -

### Data / Parameter:

**n<sub>PJ,i,y</sub>**

<table>
<thead>
<tr>
<th>Data unit:</th>
<th>-</th>
</tr>
</thead>
</table>

**Description:** Total number of project building units included in the sample for building unit category *i* in year *y*.

**Source of data:** Project participants

**Measurement procedures (if any):** -

**Monitoring frequency:** Annually
### QA/QC procedures:

- 

### Any comment:

The value of this parameter should always be larger than the minimum sample size.

### Data / Parameter:

<table>
<thead>
<tr>
<th>Data unit:</th>
<th>$N_{PJ,UNO,i,y}$ or $n_{PJ,UNO,i,y}$</th>
</tr>
</thead>
</table>
| Description: | Total number of project building units not satisfying the occupancy criterion in the population ($N_{PJ,UNO,i,y}$) or sample ($n_{PJ,UNO,i,y}$) for building unit category $i$ in year $y$. The occupancy criterion is as follows:
- Residential building units, either in a low-rise or high-rise building, are occupied, and used as a primary, year-round residence;
- Commercial and institutional building units, either in a low-rise or high-rise building, are operated on annual average at least 30 hours/week |
| Source of data: | Building survey |
| Measurement procedures (if any): | - |
| Monitoring frequency: | For the first year of the project implementation, and every third year thereafter, or more frequently |
| QA/QC procedures: | - |
| Any comment: | - |

### Data / Parameter:

<table>

| **Description:**       | • Electricity consumption of project building unit $j$ in building unit category $i$ in year $y$; or,  
                        | • Electricity consumption of the whole building, which project building unit $j$ in building unit category $i$ belongs to, in year $y$ |
| **Source of data:**    | Choose among the following options:  
                        | a) Utility billing records  
                        | b) On-site measurements |
| **Measurement procedures (if any):** | a) As per the utility metering  
                        | b) Use electricity meters |
| **Monitoring frequency:** | a) As per the utility metering  
                        | b) Continuously, aggregated at least annually |
| **QA/QC procedures:** | Check consistency of the monitored records with the records from previous monitoring intervals |
| **Any comment:**       | $EC_{PJBldg,i,j,y}$ is applicable only if the electricity consumption is monitored only at a whole building level |
### Data / Parameter:

### Data / Parameter:
NCV<sub>k, y</sub>

### Data unit:
GJ/m³

### Description:
Average net calorific value of the fossil fuel<br>consumed in year<br>y.  

### Source of data:
The following data sources may be used if the relevant conditions apply:

<table>
<thead>
<tr>
<th>Data source</th>
<th>Conditions for using the data source</th>
</tr>
</thead>
<tbody>
<tr>
<td>a) Values provided by the fuel supplier in invoices</td>
<td>This is the preferred source</td>
</tr>
<tr>
<td>b) Measurements by the project participant</td>
<td>If a) is not available</td>
</tr>
</tbody>
</table>
| c) Regional or national default value | If a) is not available  
These sources can only be used for liquid fuels and should be based on well documented, reliable sources (such as national energy balances) |
| d) IPCC default values at the upper limit of the uncertainty at 95% confidence interval as provided in Table 1.2 of Chapter 1 of Vol. 2 (Energy) of the 2006 IPCC Guidelines on National GHG Inventories | If a) is not available |

### Measurement procedures (if any):
For a) and b): Measurements should be undertaken in line with national or international fuel standards

### Monitoring frequency:
For a), b) and c): For the first year of the project implementation, and every third year thereafter  
For d): Any future revision of the IPCC Guidelines should be taken into account

### QA/QC procedures:
Verify if the values under a), b) and c) are within the uncertainty range of the IPCC default values as provided in Table 1.2, Vol. 2 of the 2006 IPCC Guidelines. If the values fall below this range collect additional information from the testing laboratory to justify the outcome or conduct additional measurements.  
The laboratories in a), b) or c) should have ISO17025 accreditation or justify that they can comply with similar quality standards

### Any comment:
Applicable only if the project activity is implemented under a programme of activities  
Note that for the NCV the same basis (pressure and temperature) should be used as for the fuel consumption

Annex 1: List of building unit categories

1. This list provides building unit categories eligible under this methodology. The list categorizes building units based on two criteria: (i) type of a building unit, and (ii) height of a whole building that the building unit belongs to.

2. Definitions of building unit types eligible under this methodology are provided below. Further, a low-rise building is defined as a building with three stories or fewer above grade, and a high-rise building with more than three stories above grade.

3. Residential building units: Building units used as one of the following dwelling purposes.
   - Single-family (low-rise or high-rise): This category includes constructions for a single family or household, such as bungalows, cottages, stand-alone houses, semi-detached houses, town houses and row houses;
   - Multi-family (low-rise or high-rise): This category includes apartments in a building that comprises of more than two apartments.

4. Commercial building units: Building units used for one of the following activities focusing on the exchange of goods and/or services for a profit.
   - Office (low-rise or high-rise): This category includes, for example, administrative and professional offices, government offices, and banks or other financial institutions;
   - Hotel (low-rise or high-rise): This category includes, for example, hotels, motels, and guest houses;
   - Warehouse & storage (low-rise or high-rise): This category includes, for example, distribution and shipping centers;
   - Mercantile & service (low-rise or high-rise): This category includes the following:
     - Retail: This category includes, for example, shopping stores for furniture, cloths, drugs, books, or building supplies, rental centers for videos or vehicles, dealer shops or showrooms for vehicles, and studios or galleries;
     - Food sales: This category includes, for example, grocery stores or food markets, gas stations with convenience stores, convenience stores, and beer, wine, liquor stores;
     - Service: This category includes, for example, auto repair shops, post offices, photocopy center, beauty parlour or barber shop, gas stations without convenience stores, cleaning, and tanning salon;
     - Other mercantile & service: This category includes mercantile & service building units that belong to none of the above categories.
   - Food service (low-rise or high-rise): This category includes, for example, restaurants or cafeterias, fast foods, bars, reception halls, and catering services;
   - Entertainment (low-rise or high-rise): This category includes, for example, cinemas, sports arenas, casinos, and night clubs.
5. Institutional building units: Building units used for one of the following activities focusing on not-for-profit services in the public's interest.

- **Education (low-rise or high-rise):** This category includes, for example, preschools or day-care centers, elementary or middle schools, colleges or universities, adult education, career or vocational training, and religious education;

- **Public assembly (low-rise or high-rise):** This category includes the following:
  - Social or meeting: This category includes, for example, community centers, lodges, meeting halls, convention centers, senior centers, student activities centers, and parliamentary buildings;
  - Culture: This category includes, for example, museums, theaters, operas, and concert halls;
  - Religious worship: This category includes, for example, temples, mosques, and churches;
  - Recreation: This category includes, for example, gymnasiums, indoor swimming pools, buildings to serve outdoor recreational facilities and outdoor swimming pools;
  - Other public assembly: This category includes public assembly building units that belong to none of the above categories.

- **Health care (low-rise or high-rise):** This category includes the following:
  - Health care: This category includes, for example, hospitals, clinics, and rehabilitation centers;
  - Nursing: This category includes, for example, nursing homes, assisted living centers, or other residential care buildings;
  - Other health care: This category includes health care building units that belong to none of the above categories.

- **Public order and safety (low-rise or high-rise):** This category includes the following:
  - Stations: This category includes, for example, police and fire stations, other public service stations for road and park maintenance, civil defence;
  - Prisons: This category includes, for example, jails, reformatories, and penitentiaries;
  - Judiciary: This category includes, for example, courthouses and probation offices;
  - Other public order and safety: This category includes public order and safety building units that belong to none of the above categories.

- **Institutional lodging (low-rise or high-rise):** This category includes, for example, retirement homes, convent or monastery, shelters, orphanage, or children's homes, halfway houses, and military barracks.
Annex 2: Sample format for baseline building survey questionnaire

**Objective:** Establishment of emissions benchmark for buildings.

**Questionnaire:** An objective questionnaire is designed as per guidance provided in this appendix.

**Methodology of conducting the baseline building survey:**

(a) Definition of project region (administrative specification);
(b) Sampling Frame: Municipal / government cadastre;
(c) Sampling Unit: Building;
(d) Sampling Method: Systematic random sampling;
(e) Sample Size: The sample size is determined as per equation (1) in the methodology;
(f) Sampling Plan: The entire set of buildings found in the cadastre covering the project region is divided into different building categories (i). The stratification of building categories (i) is carried out as per Annex I of the methodology;
(g) Mode of data collection: Interview of building administrators of the selected buildings;
(h) Frequency of surveying: Initial survey before project start, annual survey during crediting period.

I. Initial survey on baseline building units

1. Date of survey: ____/____/____ (day, month year)

2. Name of survey administrator: __________

3. Contact details of interviewed building administrator:

   a) ______________________ (name)

   b) ______________________ (telephone)

   c) ______________________ (email)

4. Building location:

   a) ______________ (municipality)

   b) __________________________ (street address) or ______ (GPS coordinates)

   c) ______ (unique baseline building identifier)

5. District heating is used for this building: ☐ No; ☐ Yes

6. Socio-economic conditions of neighbourhood: ______ (choose parameter as per methodology, provide source of information)
7. Building unit category: ____________ (select from Annex 1 of methodology)

8. Building height: ____ (number of floors above grade)

9. Number of building units in building: ____
   ________________________________ (list unique baseline building unit identifiers)

10. GFA of building units (excluding common service areas outside the physical boundaries of the building units):
    a) ___m$^2$ (in case of building unit and building being identical)
    b) ___m$^2$ for building unit # ___________ (please add lines as necessary)

11. Start of building occupancy: __/_____ (month, year)

12. Occupancy / use status of each building unit:
    a) In case of residential building units: □ Primary residence □ Secondary residence (add lines as necessary)
    b) In case of commercial and institutional building units: ____ hours/week (annual average)
       (add lines as necessary)

13. Energy and refrigerant consumption of building (list all fuel, refrigerant and energy types for three years prior to survey, specify measurement unit as appropriate, add lines as necessary, differentiate by building unit, if available)
    a) ______m$^3$/ t of fossil fuel type ____________
    b) ______MWh of electricity
    c) ______GJ of chilled/hot water
    d) ______t of refrigerant type ____________
    e) _______________________________________ Description of apportioning procedure to building units if energy consumption data are only available for the whole building

II. Annual ex-post monitoring of baseline building units during crediting period

1. Date of survey:__/__/_____ (day, month year)

2. Period covered by survey: from __/__/_____ to __/__/_____ (day, month year)

3. Name of survey administrator: ____________

4. Contact details of interviewed building administrator:
a) ______________________ (name)

b) ______________________ (telephone)

c) ______________________ (email)

5. Building location:

a) _______________ (municipality)

b) ____________________________ (street address), or: ______ (GPS coordinates)

c) ______ (unique baseline building identifier)

6. District heating is used for this building: ☐ No; ☐ Yes

7. Building has ceased to exist: ☐

8. Building has changed its function: ☐

9. GFA of building units (excluding common service areas outside the physical boundaries of the building units, to be done every third year):

a) ___m^2 (in case of building unit and building being identical)

b) ___m^2 for building unit # ___________ (please add lines as necessary)

10. Occupancy / use status:

a) In case of residential building units: ☐ Primary residence ☐ Secondary residence

b) In case of commercial and institutional building units: ____ hours/week (annual average)

11. Energy and refrigerant consumption of building (list all fuel, refrigerant and energy types for past calendar year, specify measurement unit as appropriate, add lines as necessary, differentiate by building unit, if available)

a) ______ t of fossil fuel type ____________

b) ______ MWh of electricity

c) ______ GJ of chilled/hot water

d) ______ t of refrigerant type ____________ (as per frequency specified in the methodology)

e) _______________________________ Description of apportioning procedure to building units if energy consumption data are only available for the whole building
III. Initial survey on baseline district chilled/hot water systems

1. Date of survey:__/__/____ (day, month year)

2. Name of survey administrator:__________

3. Contact details of interviewed chilled water production administrator:
   a) ______________________ (name)
   b) ______________________ (telephone)
   c) ______________________ (email)

4. District served by the chilled water/hot production: _________________________

5. Chilled/hot water production: ______ GJ of chilled/hot water

6. Energy and refrigerant consumption due to chilled water production (list all fuel, refrigerant and energy types for three years prior to survey, specify measurement unit as appropriate, add lines as necessary)
   a) ______ m³/t of fossil fuel type ______________
   b) ______ MWh of electricity
   c) ______ t of refrigerant type _____________

   In case of using geothermal heat sources, please provide
   d) ______ t methane emitted

7. Energy losses due to chilled/hot water distribution
   a) ___ %

IV. Annual ex-post monitoring of baseline district chilled/hot water systems

1. Date of survey:__/__/____ (day, month year)

2. Period covered by survey: from__/__/____ to__/__/____ (day, month year)

3. Name of survey administrator:__________

4. Contact details of interviewed chilled/hot water production administrator:

---

38 In case chilled/hot water is supplied by a district system, the building administrator does not have access to data related to chilled/hot water production. Thus, it is necessary to fill a questionnaire separate from the one for the building administrator.
a) __________________ (name)
b) __________________ (telephone)
c) __________________ (email)

5. District served by the chilled/hot water production: _______________________

6. Chilled water production: ______ GJ of chilled/hot water

7. Energy and refrigerant consumption due to chilled/hot water production (list all fuel, refrigerant and energy types for past calendar year, specify measurement unit as appropriate, add lines as necessary)
   a) _____ m³/ t of fossil fuel type _____________
   b) _____ MWh of electricity
   c) _____ t of refrigerant type _____________

   In case of using geothermal heat sources, please provide
   d) _____ t methane emitted

8. Energy losses due to chilled/hot water distribution ___ %
Annex 3: Sample format for project building survey questionnaire

Objective: Enable calculation of project emissions for project buildings.

Questionnaire: An objective questionnaire is designed as per guidance provided in this appendix.

Methodology of conducting the project building survey:

(a) Sampling Method: Systematic random sampling;

(b) Sample Size: The sample size is determined as per equation (31) in the methodology;

(c) Stratification: The entire set of project buildings is divided into different building categories \((i)\) as per Annex I of the methodology;

(d) Mode of data collection: Interview of building administrators of the buildings.

(e) Frequency of surveying: Annual survey during crediting period.

I. Annual ex-post monitoring of project building units

1. Date of survey: __/__/____ (day, month year)

2. Period covered by survey: from __/__/____ to __/__/____ (day, month year)

3. Name of survey administrator: __________

4. Contact details of interviewed building administrator:

   a) ______________ (name)

   b) ______________ (telephone)

   c) ______________ (email)

5. Building location:

   a) __________ (municipality)

   b) ______________ (street address) or _____ (GPS coordinates)

   c) _____ (unique project building identifier)

6. Confirmation of absence in the surveyed building of

   a) district heating: □ (every third year of the crediting period)

   b) cogeneration: □ (every third year of the crediting period)
c) use of CFCs as refrigerants: □ (every third year of the crediting period)

d) use of biogas: □ (every third year of the crediting period)

c) use of biomass use: □ (every third year of the crediting period)

7. Building unit category: ____________ (select from Annex 1 of methodology)

8. Building height: ____ (number of floors above grade)

9. Number of building units in building: ____

___________________________________ (list unique project building unit identifiers)

10. GFA of building units (excluding common service areas outside the physical boundaries of the building units):

   a) ___m$^2$ (in case of building unit and building being identical)

   b) ___m$^2$ for building unit # ___________ (please add lines as necessary)

11. Start of building occupancy: __/____ (month, year)

12. Occupancy / use status of each building unit:

   a) In case of residential building units: □ Primary residence □ Secondary residence (add lines as necessary)

   b) In case of commercial and institutional building units: ____ hours/week (annual average)

(Add lines as necessary)

13. Energy and refrigerant consumption of building (list all fuel, refrigerant and energy types for past calendar year, specify measurement unit as appropriate, add lines as necessary, differentiate by building unit, if available)

   a) ______ t of fossil fuel type ____________

   b) ______ MWh of electricity

   c) ______ GJ of chilled/hot water

   d) ______ t of refrigerant type ____________ (as per frequency specified in the methodology)

   c) ________________________________ Description of apportioning procedure to building units if energy consumption data are only available for the whole building
II. Annual ex-post monitoring of project district chilled/hot water systems

1. Date of survey: __/__/____ (day, month year)

2. Period covered by survey: from __/__/____ to __/__/____ (day, month year)

3. Name of survey administrator: ____________

4. Contact details of interviewed chilled water production administrator:
   a) ____________________(name)
   b) ____________________(telephone)
   c) ________________________(email)

5. District served by the chilled/hot water production: _______________________

6. Chilled water/hot production ______ GJ of chilled/hot water

7. Energy and refrigerant consumption due to chilled/hot water production (list all fuel, refrigerant and energy types for past calendar year, specify measurement unit as appropriate, add lines as necessary)
   a) ______m$^3$/t of fossil fuel type ____________
   b) ______MWh of electricity
   c) ______t of refrigerant type ____________

   In case of using geothermal heat sources, please provide
   d) ______ t methane emitted

8. Energy losses due to chilled/hot water distribution ___ %
