**CDM-MP97-A08** 

# Information note

# Development of default values for fraction of non-renewable biomass

Version 03.0

#### **COVER NOTE**

## 1. Procedural background

- 1. The Executive Board of the clean development mechanism (CDM) (hereinafter referred to as the Board), at its 116<sup>th</sup> meeting, considered the information on development of accurate and reliable region-specific default values for fraction of non-renewable biomass (f<sub>NRB</sub>) that can be applied in methodologies for clean cooking and requested the Methodologies Panel (MP) to develop subnational/regional values of f<sub>NRB</sub>, building on scientific studies and engaging external experts. The Board highlighted that such default values should be consistent with the methods contained in "TOOL30 Calculation of the fraction of non-renewable biomass" (hereinafter referred to as TOOL30). In this regard, the Board requested the MP to prepare a concept note based on the work undertaken for consideration by the Board at a future meeting. The Board further requested the MP to propose a revision to TOOL30 and/or related methodologies/tools if there is a need to further clarify and/or revise elements of TOOL30 or related methodologies/tools, in light of the work undertaken on default values.
- 2. The MP launched a call for stakeholder inputs on the info note: "Default values for fraction of non-renewable biomass (f<sub>NRB</sub>)", as contained in MP 92, Annex 7, from 13 October 2023 to 31 January 2024.
- 3. At its  $122^{nd}$  meeting (EB 122 meeting report, para. 23), the Board took note of the information note on "Stakeholder inputs on the review of clean cooking methodologies including estimation of  $f_{NRB}$  values", as contained in annex 4 to the MP 94 meeting report, and requested the MP to continue to consider the issue and make a recommendation at its next meeting for the consideration of the Board.
- 4. The MP launched a call for stakeholder inputs on the updated revised report from the experts on the "Default values for fraction of non-renewable biomass (f<sub>NRB</sub>)" from 21 June to 9 August 2024.
- 5. At its 123<sup>rd</sup> meeting (EB 123 meeting report, para. 28), the Board took note of the information note on "Stakeholder inputs on the review of clean cooking methodologies including estimation of f<sub>NRB</sub> values", as contained in annex 4 to the MP 95 meeting report, and requested the MP to continue to consider the issues and make a recommendation for the consideration of the Board at its next meeting.
- At its 124<sup>th</sup> meeting (EB 124 meeting report, para. 30), the Board took note of the information note "Development of default values for fraction of non-renewable biomass", as contained in annex 3 to the MP 96 meeting report, and taking into account the feedback provided by the Board at this meeting, requested the MP to further work on the following:
  - (a) Explore further the data on the calculation of urban fraction of non-renewable biomass ( $f_{NRB}$ ) and the localisation of wood harvesting for charcoal production supplying the urban areas; and
  - (b) Assess the optimal geographical disaggregation for the estimation of f<sub>NRB</sub> values, taking into account e.g. the uncertainty level of estimates at different geographical

levels and fuelwood and charcoal flows between different sub-national jurisdictions or across national borders.

7. The Board requested the MP to revise the information note for consideration by the Board at its next meeting.

#### 2. Purpose

8. The purpose of this information note is to address the mandate provided at EB 116 (i.e. develop subnational, national, regional and global default values of f<sub>NRB</sub>) and provide a recommendation to the Board on the default values of f<sub>NRB</sub> and TOOL33: Default values for common parameters" (hereinafter referred to as TOOL33). Further, this information note provides MP's response to issues raised by the Board at EB 124.

# 3. Key issues and proposed solutions

- 9. CDM programmes of activities (PoAs) have a high share of efficient cookstove projects which reduce consumption of non-renewable biomass. The f<sub>NRB</sub>, as opposed to what can be sustainably harvested, is one of the key parameters for calculating emission reduction in the methodologies for efficient cookstoves such as "AMS-II.G. Energy efficiency measures in thermal applications of non-renewable biomass", along with other parameters, such as the annual consumption of woody biomass and efficiency of devices.
- 10. In accordance with TOOL30 for estimating f<sub>NRB</sub>, project participants currently have three options when determining f<sub>NRB</sub> values: (a) Using a default value of 0.30; (b) Using preapproved default country-specific values, known as the standardized baselines, where available; or (c) Calculating project specific f<sub>NRB</sub> values using TOOL30.
- 11. The current default value of 0.30 that can be applied globally was adopted by the Board at its 97<sup>th</sup> meeting as a conservative default, taking into account literature available at that time<sup>1</sup>.
- 12. Over time, it became apparent that this universal default value of 0.30 has seldom been applied in CDM projects and PoAs. Instead, most projects used either of the other two options which yielded much higher and therefore less conservative values of the f<sub>NRB</sub>. In addition, the data used to establish that default value, by now over a decade old, are likely to be outdated as well as some of the data is based on very limited study and anecdotal reporting.
- 13. In that context, the EB 116 requested the MP to develop subnational/regional values of f<sub>NRB</sub>. External experts have been engaged to assist the work of the MP on this matter. The report of the external experts is available in Appendix 3 to this document.
- 14. The revisions to the information note are highlighted in two colors: yellow highlights indicate changes introduced at MP96 and submitted for consideration at EB 124; while green highlights reflect additional changes made at MP97, and submitted for consideration of the Board at EB 125.

<sup>1</sup> For example, Bailis, R.; Drigo, R.; Ghilardi, A. & Masera, O. (2015). The carbon footprint of traditional woodfuels. Nature Climate Change, 5(3), pp. 266–272. This paper estimated that global *fNRB* value was 27 to 34 per cent, with large geographic variations.

- 15. It may be noted that with regard to issues raised at EB 124, these issues were not addressed by TOOL30: Calculation of the fraction of non-renewable biomass, and/or other similar calculations undertaken to develop f<sub>NRB</sub> values. The MP considers the approach used in MoFuSS as an advancement in terms of accuracy and conservativeness compared to the f<sub>NRB</sub> values obtained using the existing approach provided in the TOOL30. However, the MP welcomes stakeholders to submit new methodological approaches for calculation of f<sub>NRB</sub> values that result in further advancements in terms of accuracy and conservativeness for consideration by the Board.
- 16. With regard to the clarification requests raised at EB 124, the additional clarifications are as below:
  - (a) f<sub>NRB</sub> for urban areas and charcoal production: MoFuSS estimates the impacts of demand at the point of woodfuel harvesting, not limited to the area where consumption occurs. Further, urban demand is mainly met from commercial woodfuel, which is typically harvested over wider areas and transported by road to areas of consumption. This implies that urban fuelwood demand will impact harvesting in areas outside of administrative units with urban areas. While the calculation of f<sub>NRB</sub> for an administrative unit is based on all harvest and demand within that administrative unit. As a result, urban areas show low f<sub>NRB</sub> values despite their high demand of woodfuel. Whereas most rural demand is supplied through non-commercial woodfuel collected from areas typically accessible by foot. Thus to improve further the calculation of urban f<sub>NRB</sub>, additional work would have to be undertaken at a minimum to map charcoal production and environmental degradation; to predict future charcoal production risk areas; to understand local actors and governance dynamics. Collecting the data and preparing maps is estimated to take at least 24 months.
  - (b) Optimal geographical disaggregation:
    - The MoFuSS model offers an improvement over the previous TOOL30 and models, in that the woodfuel supply area for a demand center is defined with the distances from which fuelwood can be collected. This supply distance is defined by the following factors: commercial or domestic demand; for commercial fuelwood - the ease of collection and transport (depending on the transport infrastructure). Thus the supply distances for a demand centre are identified by the model. This depends on assumptions for the share of commercial fuelwood, for road infrastructure, for the probability of demand coming from various harvesting areas etc. Unless the project proponents have detailed information on the sources of wood for a particular demand centre, it is difficult to define a geographical area that is most appropriate (in this case the second administrative level, which in most countries are called districts, or the first administrative level). But within a country the MoFuSS model doesn't restrict the supply of fuelwood to demand centres by administrative boundaries. One of the main improvements of MoFuSS over earlier methods like WISDOM is that it does not require optimal geographical disaggregation or fixed 'woodfuel sheds', instead, it sets areas where wood is harvested around demand centers. Assessing an "optimal geographical disaggregation for the estimation of f<sub>NRB</sub>" would require empirically determined f<sub>NRB</sub> values for specific areas, to which the model results can be compared to and adjusting spatial boundaries to improve model accuracy however, such empirical values do not exist for any location. MoFuSS

aggregates raster outputs from business as usual (BaU) simulations at different administrative levels to estimate regional trends. However, these results must be interpreted cautiously. Woodfuels harvested in one administrative unit may supply demand centers in another unit, especially in smaller administrative units. Unless the project developer knows the maximum sourcing distance, national-level values should be used to account for all potential woodfuel flows. On the MoFuSS webpage, users can draw or upload custom Areas of Interest (AoIs), and basic statistics will be calculated instantly, following the same recommendation.

- (ii) A key limitation of any analysis or approach is the lack of detailed data on demand and supply, and specially so regarding charcoal. The MoFuSS model uses the existing data. Most of this data is available at national levels except the forest areas in a country. MoFuSS uses the existing data more efficiently. Based on the available data, the model assesses the influence area for demand centres from where the fuelwood for direct use and charcoal production could be supplied. This is then used for calculating the f<sub>NRB</sub> values at different levels for national sub-regions. The model needs to be adapted to be able to capture the trade flows across national and sub-regional boundaries; in addition the availability of data is a limitation. To include detailed data of flows of fuelwood and charcoal among national sub-regions, while possible, would require significant additions to the model to capture the data. This exercise would require significant additional resources and time.
- (c) Modeling fuelwood and charcoal flows between multiple subnational jurisdictions or across national border is not possible within the scope and timeframe of the current framework.

## 4. Impacts

17. The sub-national national and regional (continental) and global default values of f<sub>NRB</sub> will ensure the reliability of calculating emission reductions, reduce transaction cost and facilitate the implementation of CDM project activities and PoAs in the household cookstove or water purification sector.

# 5. Subsequent work and timelines

18. Based on the mandate received from the Board, the MP will undertake further work.

#### 6. Recommendations to the Board

19. The MP recommends that the Board approve the default sub-national, regional (continental) and national and global default values of f<sub>NRB</sub> for the countries respectively shown in Table 1 and 2 of Appendix 1. Table 2 and Table 3 of Appendix 2. The MP agreed to include these default values in the updated version of TOOL33<sup>2</sup>. National values may be used if it can be justified that the project activity has an impact on fuelwood harvesting all over the host country. Where national sub-national values are not listed in the aforementioned tables, the project participant may use the relevant regional value in Table

<sup>&</sup>lt;sup>2</sup> Refer to Annex 1 of MP 97 meeting report.

4 of the Appendix 2 the regional (continental) values. the global default value. Alternatively, stakeholders may submit new methodological approaches for the calculation of f<sub>NRB</sub> values that result in further advancements in terms of accuracy and conservativeness, for consideration by the Board. Further, stakeholders may also choose to propose different default values through a request for revision to TOOL33 as per existing procedures<sup>3</sup>.

- 20. The MP also recommends that  $f_{NRB}$  for project activities in urban areas and in countries where more than 20% of the woodfuel consumed in the country is imported, the weighted average of the fNRB of the host country and the  $f_{NRB}$  of countries from where woodfuel is imported shall be used to calculate a relevant value for the project activity.
- 21. Use of the sub-national values are recommended in principle, unless the applied methodology/ies specifies the level (e.g. national). In addition, where sub-national values are not listed, the national value may be used. In cases where neither the sub-national or national values are listed, the regional value may be used.

The choice between the national or sub-national level for the f<sub>NRB</sub> shall be selected depending on the geographical boundary of the project activity. The final choice for the relevant f<sub>NRB</sub> value may be made at the issuance stage once the area of implementation of the project activity can be observed.

- 22. The MP recommends the discontinuation of TOOL30 with effect from 1 January 2026.
- 23. The MP will has updated the relevant methodologies where the f<sub>NRB</sub> values are referred to and submitted these methodologies for the consideration of the Board at EB125 as annexes to the MP97 meeting report.
- 24. The MP is also of the view that the modelling fuelwood savings scenarios (MoFuSS) model could be used by the Project Participants to define the appropriate geographic area around the project site to develop a project specific f<sub>NRB</sub>. The MoFuSS model is open access and accessible to public.

#### The MP seeks further mandate to

- (a) Undertake additional work on the calculation of f<sub>NRB</sub> using the marginal approach; the f<sub>NRB</sub> values estimated so far determines the share of the current fuelwood harvest taking place in elemental areas (pixels) where overharvesting can be observed. The marginal f<sub>NRB</sub> value reflects the fact that reduction of fuelwood harvest triggered by a project activity does not uniformly impact the harvesting activity in each elemental area uniformly and therefore results in a different f<sub>NRB</sub> for the reduced amount of fuelwood due to the implementation of the project activity. MoFuSS can be used to provide some information on this issue;
- (b) Explore further the data on the calculation of urban f<sub>NRB</sub> and the localisation of wood harvesting for charcoal production supplying the urban areas; and

<sup>&</sup>lt;sup>3</sup> Development, revision and clarification of baseline and monitoring methodologies and methodological tools v02.1.

<sup>&</sup>lt;sup>4</sup> AMS-I.E.: Switch from non-renewable biomass for thermal applications by the user; AMS-II.G.: Energy efficiency measures in thermal applications of non-renewable biomass; AMS-III.AV.: Low greenhouse gas emitting safe drinking water production systems; AMS-III.BG.: Emission reduction through sustainable charcoal production and consumption.

- (c) Assess the optimal geographical disaggregation for the estimation of f<sub>NRB</sub> values taking into account e.g. the uncertainty level of estimates at different geographical levels and fuelwood and charcoal flows between different sub-national jurisdictions or across national borders.
- 25. The MP noted that the availability of data on demand for woodfuel and on the growth rates of forests is limited, which adds to the uncertainty of the f<sub>NRB</sub> values. The MP would like to request the Board to make a call to other agencies and entities to enhance their efforts to collect such data.

## 1. Procedural background

- 1. The Executive Board of the clean development mechanism (CDM) (hereinafter referred to as the Board), at its 116<sup>th</sup> meeting, considered the information on development of accurate and reliable region-specific default values for fraction of non-renewable biomass (f<sub>NRB</sub>) that can be applied in methodologies for clean cooking and requested the Methodologies Panel (MP) to develop subnational/regional values of f<sub>NRB</sub>, building on scientific studies and engaging external experts. The Board highlighted that such default values should be consistent with the methods contained in "TOOL30 Calculation of the fraction of non-renewable biomass" (hereinafter referred to as TOOL30). In this regard, the Board requested the MP to prepare a concept note based on the work undertaken for consideration by the Board at a future meeting. The Board further requested the MP to propose a revision to TOOL30 and/or related methodologies/tools if there is a need to further clarify and/or revise elements of TOOL30 or related methodologies/tools, in light of the work undertaken on default values.
- 2. The MP launched a call for stakeholder inputs on the info note: Default values for fraction of non-renewable biomass (f<sub>NRB</sub>)", as contained in MP 92 Annex 7 from 13 October 2023 to 31 January 2024.
- 3. At its 122<sup>nd</sup> meeting (EB 122 meeting report, para. 23), the Board took note of the information note on "Stakeholder inputs on the review of clean cooking methodologies including estimation of f<sub>NRB</sub> values", as contained in annex 4 to the MP 94 meeting report, and requested the MP to continue to consider the issue and make a recommendation at its next meeting for the consideration of the Board.
- 4. The MP launched a call for stakeholder inputs on the updated revised report from the experts on the "Default values for fraction of non-renewable biomass (f<sub>NRB</sub>)" from 21 June to 9 August 2024.
- 5. At its 123<sup>rd</sup> meeting (EB 123 meeting report, para. 28), the Board took note of the information note on "Stakeholder inputs on the review of clean cooking methodologies including estimation of f<sub>NRB</sub> values", as contained in annex 4 to the MP 95 meeting report, and requested the MP to continue to consider the issues and make a recommendation for the consideration of the Board at its next meeting.
- At its 124<sup>th</sup> meeting (EB 124 meeting report, para. 30) the Board took note of the information note "Development of default values for fraction of non-renewable biomass", as contained in annex 3 to the MP 96 meeting report, and taking into account the feedback provided by the Board at this meeting, requested the MP to further work on the following:
  - (a) Explore further the data on the calculation of urban fraction of non-renewable biomass ( $f_{NRB}$ ) and the localisation of wood harvesting for charcoal production supplying the urban areas; and
  - (b) Assess the optimal geographical disaggregation for the estimation of f<sub>NRB</sub> values, taking into account e.g. the uncertainty level of estimates at different geographical levels and fuelwood and charcoal flows between different sub-national jurisdictions or across national borders.
- 7. The Board requested the MP to revise the information note for consideration by the Board at its next meeting.

#### 2. Purpose

8. The purpose of this information note is to address the mandate provided at EB 116 (i.e. develop subnational, national, regional, global default values of f<sub>NRB</sub>) and provide a recommendation to the Board on the default values of f<sub>NRB</sub> and TOOL30.

## 3. Key issues and proposed solutions

#### 3.1. Existing approach to calculate fNRB

- 9. CDM programmes of activities (PoAs) have a high share of efficient cookstove projects which reduce consumption of non-renewable biomass. The f<sub>NRB</sub>, as opposed to what can be sustainably harvested, is one of the key parameters for calculating emission reduction in the methodologies for efficient cookstoves such as "AMS-II.G. Energy efficiency measures in thermal applications of non-renewable biomass", along with other parameters such as the annual consumption of woody biomass and efficiency of devices.
- 10. In accordance with TOOL30 for estimating f<sub>NRB</sub>, project participants currently have three options when determining f<sub>NRB</sub> values: (a) Using a default value of 0.30; (b) Using preapproved default country-specific values, known as the standardized baselines, where available; or (c) Calculating project specific f<sub>NRB</sub> values, using TOOL30.
- 11. The current default value of 0.30 that can be applied globally was adopted by the Board at its 97<sup>th</sup> meeting as a conservative default, taking into account literature available at that time<sup>1</sup>.
- 12. Over time, it became apparent that this universal default value of 0.30 has seldom been applied in CDM projects and PoAs. Instead, most projects used either of the other two options which yielded much higher and therefore less conservative values of the f<sub>NRB</sub>. In addition, the data used to establish that default value, by now over a decade old, are likely to be outdated as well as some of the data is based on very limited study and anecdotal reporting.
- 13. In that context, the EB 116 requested the MP to develop subnational/regional values of f<sub>NRB</sub>. External experts have been engaged to assist the work of the MP on this matter. The draft report of the external experts is available in Appendix 2 3 of this document.
- 14. The sections below describe the approach used by the external experts to develop new default values of f<sub>NRB</sub>.

# 3.2. Key changes between the report submitted in October 2023 and the current report

15. After the preliminary f<sub>NRB</sub> results for Sub-Saharan Africa were submitted to the Board in October 2023, several key assumptions were changed in response to stakeholders' inputs. In addition, the scope of the assessment was expanded to encompass the entire Global South. These changes required the use of different input datasets and several modifications to the model itself.

<sup>&</sup>lt;sup>1</sup> For example, Bailis, R.; Drigo, R.; Ghilardi, A. & Masera, O. (2015). The carbon footprint of traditional woodfuels. Nature Climate Change, 5(3), pp. 266–272. This paper estimated that global *fNRB* value was 27 to 34 per cent, with large geographic variations.

- 16. For clarity, the most critical modifications and new datasets recently introduced, ranked by their impact on the differences between the new results and those presented in October 2023 for Sub-Saharan Africa, are as follows:
  - a) Population maps: Transitioned from HSRL to WorldPop (https://www.worldpop.org) to include countries not covered by HSRL, such as China and others in Asia and Africa;
  - b) Revegetation Growth Curves: The submodule for generating revegetation growth curves was completely recoded. In the previous approach, growth functions were estimated based on the IPCC's biomass stock estimations. A few issues were identified e.g. in very arid areas, it was found that available biomass was less than the model's minimum harvestable threshold (1 tonne/ha for charcoal production and 0.1 tonne/ha for gathered fuelwood), which caused the model to output physically impossible negative harvest and f<sub>NRB</sub> values in a small number of pixels²/elemental areas. This was corrected to avoid those outputs;
  - c) Sub-region trade in Sub-Saharan Africa: The information from reviews of international fuelwood trading in Sub-Saharan Africa was used to redefine the boundaries across which trading can take place;
  - d) Woodfuel consumption: All fuelwood and charcoal demand figures have been thoroughly reviewed in response to stakeholder inputs.

#### 3.3. Approach to develop new default values of fNRB

- 17. The assessment of f<sub>NRB</sub> values was conducted using the latest available data on woody biomass supply and demand with the Geographic Information System (GIS) based model called modelling fuelwood savings scenarios (MoFuSS). The model relies on the same basic concepts used by the Woodfuels Integrated Supply/Demand Overview Mapping (WISDOM) methodology, used to derive the results on which the current default value of 0.3 is based, with several key differences. Where WISDOM uses a snapshot in time, the MoFuSS model runs simulations, which allow users to compare intervention (i.e. actions to reduce extraction on non-renewable biomass such as through efficient cook stove projects) and non-intervention scenarios that incorporate dynamic variables such as population growth, urbanization, and land cover change.
- 18. In the first phase of the assessment, the model was run for 43 countries in Sub-Saharan Africa. These countries/regions were selected as they account for the large majority of CDM projects and PoAs in the pipeline. Subject to guidance from the Board, work will continue to be conducted for the remaining countries/regions in the world; with the possibility of further updates given new global datasets and assumptions become available in the coming years.
- 19. There are similarities and differences in the approach used in the assessment and the approach defined in TOOL30. For example:
  - (a) While TOOL30 defines biomass consumption on a jurisdictional basis (e.g. districts, counties, or countries), the model used in the assessment calculates

<sup>&</sup>lt;sup>2</sup> Pixels are the smallest unit of a digital image or display. In relation to elemental areas, a pixel represents a discrete elemental area on a screen or sensor, where each pixel carries a single colour or intensity value.

it at pixel level (tonnes of dry biomass per hectare or km²) and then uses this data to derive results at larger aggregation levels;

- (b) Both TOOL30 and the MoFuSS use biomass growth parameters such as Mean Annual Increment (MAI) and Current Annual Increment (CAI) respectively, to define long-term average wood growth. In case of TOOL30 biomass growth parameters are applied to the entire land cover categories regardless of their standing stock. In contrast, the new model relies on growth functions, which are specific to land cover type and ecological zone and vary with current stock levels. The model applies these functions at the pixel level, so that every pixel has a unique woody biomass production function. Therefore, it is expected that the model simulates biomass harvest and regrowth after harvest more realistically;
- (c) TOOL30 only considers accessibility in the sense that it removes protected areas from consideration of biomass supply. MoFuSS also accounts for protected areas but goes further by considering physical accessibility based on topographical features and the effort that woodfuel users must expend to access sources of woody biomass.
- 20. There are multiple ways to use the changes in biomass simulated by MoFuSS to estimate f<sub>NRB</sub>. In this assessment, f<sub>NRB</sub> has been estimated within a given administrative boundary by identifying pixels within the boundary that experience biomass losses during a specific timespan. This wood loss is defined as non-renewable biomass or NRB. To estimate f<sub>NRB</sub>, the sum of losses occurring within the administrative boundary of interest is divided by the total biomass harvest within that same boundary. Please refer to the <u>supplementary material of Ghilardi et al 2016</u> for a detailed description of how harvest events and natural regrowth of woody biomass interact in MoFuSS over space and time to render pixel-based results of NRB.
- 21. In this assessment, the following steps were taken to develop fnrb values:
  - (a) Create maps of woody biomass use from 2010 to 2030, using population distribution maps, and woodfuel demand scenarios;
  - (b) Create maps depicting where the woody biomass from the previous step is coming from (i.e., where it is being harvested and/or collected in each year), using accessibility functions that integrate recent globally harmonized maps of land cover, biomass/carbon stocks, roads, rivers, elevation, and protected areas; this is calculated for each and every single place using biomass;
  - (c) Create maps of the potential regrowth and/or replenishment of woody biomass in natural and anthropic ecosystems respectively, after being harvested for fuelwood or charcoal:
  - (d) Generate maps of woody biomass harvest, NRB, and f<sub>NRB</sub> between 2010 and 2030, at both the pixel and administrative level.

#### 3.3.1. Key assumptions in MoFuSS Estimation of woody biomass supply and accessibility

22. The MoFuSS relies on several dozen parameters to model land cover change associated with woodfuel harvesting. The main assumptions that MoFuSS uses to estimate non-

https://docs.google.com/document/d/140duZZaBIUuCG7nvgHwsdw7Wkm2Nce7cenEpEHEvgql/edit.

renewable biomass demand in a given locality are listed below. Full details of the following parameters are in the Appendix 3:

- (a) Biomass stocks: This data informs how much biomass exists in a pixel in the initial year of the simulation, which contributes to the available supply for harvesting and the potential for future growth. There are several global maps of above-ground biomass (AGB) available. Further details are provided in the Appendix 3 (Para 23);
- (b) Biomass growth functions: These functions rely on two important parameters: annual growth rate and maximum stock within each pixel. We use the following logistic (sigmoidal) growth function to simulate woody biomass growth in each pixel and land-cover type;

$$AGB_{(t+1)i,j} = AGB_{(t)i,j} + AGB_{(t)i,j} \cdot r_{max,j} \cdot \left(1 - \frac{AGB_{(t)i,j}}{K_j}\right)$$

Where:

o i and j are indices for pixel i in land cover type j

- ABG<sub>(t)i,j</sub> or ABG<sub>(t+1)i,j</sub> aboveground wood biomass in pixel i and land cover j
  at time t or t+1
- $\circ$  r<sub>max,j</sub> is the slope at the inflection point of the sigmoidal growth function, which determines the maximum growth rate of woody biomass in each land-cover type  $j^5$
- K<sub>j</sub> is the maximum woody biomass in land-cover type j (or "carrying capacity");
- Biomass consumption: Both current and future biomass consumption are contributors to f<sub>NRB</sub>. Spatially modeling the impacts of biomass consumption requires estimates of the quantity consumed and the location of consumers. To estimate the quantity of wood and charcoal consumed, two simple parameters are taken into consideration: the number of users and the amount per user. The number of wood and charcoal users is based on WHO's recently updated "Global Household Energy Model", which projects the number and percentage of people using primary household cooking fuels in rural and urban areas of low- and middleincome countries.<sup>6</sup> By not accounting for stacking, uncertainty in woodfuel demand may be introduced. However, it is unclear whether this leads to underestimates or overestimates. For example, a fraction of the people counted as "primary charcoal users" may actually cook some of their meals with LPG or fuelwood and use less charcoal than people counted as "primary charcoal users" who do not stack with other fuels. In that case, the charcoal consumption could be overestimated. By the same token, a fraction of the people counted as "primary LPG users" may cook with some of their meals with charcoal and use less LPG than people counted as "primary LPG users" who do not stack with other fuels. This could lead to an underestimation of charcoal consumption. The same applies to other categories of

Pixel size can vary, but models are generally limited by the lowest resolution input file. For our regional or global model, we use 1km x 1km pixels. However, for sub-national or project-scale models we could use higher resolutions like 100m or 30m.

Note, r<sub>max</sub> is not a direct estimate of the maximum growth rate. Rather, it is a parameter proportional to the maximum growth rate such that maximum growth equals the product [¼ r<sub>max</sub> K].

<sup>&</sup>lt;sup>6</sup> Urban woodfuel users rely primarily on commercially supplied fuelwood and charcoal, which is usually transported by road from distant rural areas. Rural users generally gather wood from nearby. These different harvesting practices result in different geographic patterns of impacts, which we model using different algorithms.

primary fuel users. There is very little reliable data on fuel consumption among fuelstacking households;

- (d) Residential, commercial and industrial woodfuel consumption.
- 23. Biomass stocks data tells us how much biomass exists in a pixel in the initial year of the simulation, which contributes to the available supply for harvesting and the potential for future growth. Among the several global maps of above-ground biomass available that could be used in the model, the dataset provided by the World Conservation Monitoring Centre (WCMC) was used. The map shows above- and below-ground carbon stocks in tonnes per hectare from 2010 and the resolution is 300m.
- 24. The biomass growth functions rely on two important parameters: annual growth rate and maximum stock within each pixel. The specific growth functions were used to simulate woody biomass growth in each pixel by land-cover type and ecological zone.
- 25. The model focuses on stocks and growth rates of above-ground biomass, the main carbon pool on which woodfuel users depend. However, other pools of terrestrial carbon like soil organic carbon (SOC) and dead organic matter (DOM) may be affected by woodfuel harvesting, particularly if harvesting leads to forest degradation or deforestation. The model does not account for changes in SOC and only addresses DOM indirectly.

#### 3.3.2. Estimation of current and projected demand for woodfuel

- 26. Both current and future biomass consumption are contributors to fnrb. Spatial modelling of the impacts of biomass consumption requires the estimates of the quantity consumed and the location of consumers. To estimate the quantity of fuelwood and charcoal consumed, the model relied on two simple parameters: the number of users and the amount per user. The number of fuelwood and charcoal users is based on WHO's recently updated "Global Household Energy Model", which projects the number and percentage of people using primary household cooking fuels in rural and urban areas of low- and middle-income countries.<sup>7</sup>
- 27. The model focuses primarily on residential woodfuel demand. In some countries, wood may be consumed by formal and cottage industries as well as commercial establishments. The model does not include these sources of demand for several reasons: first, because there is no reliable data for the use of wood by cottage industries and informal such as brickmaking, fish smoking, beer brewing; second, while FAO publishes data on industrial roundwood production, in most countries in sub-Saharan Africa, this accounts for less than 10% of the overall wood harvest.
- The MoFuSS model focuses primarily on residential woodfuel demand. In some countries, there may be industrial or commercial use of wood that affects tree cover. In earlier versions of MoFuSS, that data was omitted because of a lack of reliable data that would allow mapping of demand in the same way that residential demand is mapped (described below). However, in response to public comments, non-residential woodfuel demand from commercial entities like hotels and restaurants, public institutions like schools, prisons, and military barracks, and cottage industries like brick burning, ceramics, beer brewing, and fish smoking among others were reviewed. To include these sources of demand, limited literature review was undertaken that focused on sub-Saharan Africa.
- 29. Accessibility to woody biomass was also accounted for by defining "friction" maps that represent the effort that wood consumers must expend to travel to a given supply area.

World Health Organization. "Household Air Pollution Data." Air pollution data portal, 2021. https://www.who.int/data/gho/data/themes/air-pollution/household-air-pollution.

These maps are derived by integrating road and river networks, land cover characteristics, elevation, and protected areas.

#### 3.3.3. Other considerations

30. Use of deforestation by-products: There are very few studies that have measured the share of woody biomass cleared for agriculture that is used as firewood or charcoal. In this assessment, it is assumed that 70% of the woody by-products of land clearance is accessible in a given year, but that it is only available that year. This assumption has a small impact on the overall results but may have a significant impact on f<sub>NRB</sub> estimations being conservative in locations that experience high rates of tree cover loss in densely populated areas. When running the model for this study, this function was not activated because the algorithms used were not effective across very large regions.

Most countries included in this analysis experience some annual loss of tree cover, which may contribute to long-term deforestation. These losses are identified by tracking annual changes in canopy cover using remotely sensed data. Tree removals identified by remotely-sensed changes in canopy cover are typically caused by land clearance for large-and small-scale agricultural expansion rather than woodfuel harvesting. However, in some situations, the by-products of land clearance are used for firewood or charcoal production. When this occurs, the harvested biomass is non-renewable because land-clearance for agriculture makes it difficult for trees to regenerate; however, the biomass does not contribute to f<sub>NRB</sub> because the trees would have been removed regardless of woodfuel demand. Thus some fraction of demand might be satisfied with non-renewable biomass that does not contribute to f<sub>NRB</sub>. The MoFuSS model includes an optional module that simulates these processes and adjusts f<sub>NRB</sub> results accordingly. However, for this assessment, this feature was not used due to a variety of reasons, which are explained in the experts' report<sup>8</sup>.

- 31. Treatment of Protected Areas: Protected areas add some uncertainty because they often contain large stocks of biomass, but the extent to which the biomass is accessible for use as woodfuel is unclear. Some protected areas are completely inaccessible, others may be used for low-level extractive activities like collecting wood for household use, and still others might be legally inaccessible, but easily exploited due to poor enforcement. In this assessment, it was considered that all protected areas are equally difficult (but not impossible) to access for both self-collection and commercial extraction. This was accomplished by increasing the "friction" or effort required to travel within the boundaries of protected areas relative to unprotected areas with similar terrain. For this assessment, friction was set at 90%, which means that the likelihood of wood harvesting within protected areas was only 10% that of unprotected areas with similar terrain.
- 32. National boundaries and trade: The sustainability of woodfuel consumption within national boundaries can be affected by transboundary trade. For example, if woodfuel is imported to Country A from neighbouring Country B, it relieves pressure on domestic sources of woody biomass in Country A, but increases pressure on domestic sources of woody biomass in Country B. The MoFuSS model can accommodate transnational trade; however, it is difficult to model because there is no reliable data to verify the results. In addition, for this analysis, Africa was divided into four sub-regions (East, Central, Southern and West) to reduce the computing time necessary for each modelling run. Thus, while transborder trade could occur between countries within each region, it could not occur between countries in separate regions, even if they share a common border such as Chad and Niger or Cameroon and Nigeria, because they were modelled separately. Modelling

<sup>8</sup> https://cdm.unfccc.int/public\_inputs/2024/202406/index.html.

the entire SSA region in one simulation will be carried out in the near future. For example, if Country-A has a major source of demand like a large urban center close to its border with Country-B, then it is possible that Country-A imports charcoal from Country-B. If that occurs, then Country-A's woodfuel supply-demand balance could be affected favorably because those imports would reduce pressure on A's own resources. By the same token, Country-B's balance would be affected negatively by the additional removals.

- 33. In theory, MoFuSS can accommodate transnational trade; however, this is difficult in practice because there is no reliable data quantifying the magnitude of the trade. FAO's forest statistics database includes woodfuel imports and exports, but the accuracy of this data is unclear and there is no information about trading partners.
- 34. In this analysis, separate regional models with semi-permeable national borders have been run, resulting in some international flow of woodfuels within each region, but no flows between regions. Within regions, crossing borders adds "friction" or travel time for wood suppliers, making it more costly, but not impossible, for people to access wood in neighboring countries. The final model includes a mix of individual countries and countries clustered together to accommodate trade, where it is suspected to be a significant fraction of overall woodfuel consumption.

#### 3.4. Results of fNRB values

35. f<sub>NRB</sub> is defined at the pixel level for a given time period as:

$$fNRB_{(t=n),j} = \frac{NRB_{(t=n),j}}{H_j}$$
 Equation (1)

Where:

 $fNRB_{(t=n),j}$  = Fraction of non-renewable biomass (fraction or %) in pixel j during the simulation period of "n" years

 $NRB_j$  = Quantity of non-renewable biomass harvested in pixel j during the

simulation period of "n" years

 $H_j$  = Total consumption of woody biomass in pixel j during the simulation period of "n" years

And

$$NRB_{t=n,j} = \begin{cases} 0 \text{ if } AGB_{t=n,j} \ge AGB_{t=0,j} \\ AGB_{t=n,j} - AGB_{t=0,j} \text{ if } AGB_{t=n,j} < AGB_{t=0,j} \end{cases}$$
 Equation (2)

Where:

 $AGB_{t=0,j}$  = Above ground woody biomass in pixel j in the initial year of interest  $AGB_{t=n,i}$  = Above ground woody biomass in pixel j in the final year of interest

- 36. The model simulates the supply and demand for the period 2010 2050. This is used to estimate the  $f_{NRB}$  values, which can be defined for the entire simulation, or divided into smaller time periods. This experts' report (in Appendix 2) presents the  $f_{NRB}$  results for the period 2020 2030 only.
- 37. To be applied in projects or programmes of activity, f<sub>NRB</sub> must be aggregated from pixel-based values to a geographic area that is appropriate for the scale of the intervention, which may be national or sub-national. To do this, the model aggregates NRB in each

pixel during the simulation period and divides that by total consumption during the same time period within the same boundary.

$$fNRB_{(t=n),project\;area} = \sum_{j} NRB_{(t=n),j} / \sum_{j} H_{j}$$
 Equation (3)

- 38. Figures 1, 2 and 3 below illustrate spatial averages of f<sub>NRB</sub> by national and sub-national administrative boundaries. These results are mathematically derived from spatial raster maps of woody biomass harvesting that leads to loss of tree cover. (the first administrative level and the second administrative level) boundaries for 43 countries in Sub-Saharan Africa. Appendix 1 2 shows a summary of results at the national level.
- 39. The global average f<sub>NRB</sub> of the 90 75 countries included in the assessment is 32% ±0.2% ± 18% (spatial mean). ± standard deviation).
- Regionally, Sub-Saharan Africa (SSA) has the highest f<sub>NRB</sub>, at 40% +/- 0.3%39% ± 17%, followed by Latin America and Asia, with 323% +/- 0.8% ± 14% and 18% +/- 0.3%47% ± 21% respectively. To estimate this variation, 30 scenarios were run by varying the value of Rmax. These Rmax values were derived from IPCC 2019 information. It needs to be noted that the information used in IPCC has high uncertainty which is reflected in the standard deviations in the f<sub>NRB</sub> values.

Table 1. Regional (Continental) fnrb values

Region	f <sub>NRB</sub> (%)
Asia	1 <mark>8 7</mark>
Latin America	3 <mark>23</mark>
Sub-Saharan Africa	<mark>40 <mark>39</mark></mark>

41. At the national level, most of the f<sub>NRB</sub> values range between 1% and 70%, with the interquartile range (25%-75%) falling between 21% and 40%. The highest national f<sub>NRB</sub> estimates occur in semi-arid countries in the Sahel, followed by several countries in East and Southern Africa and East Asia.

- 43. To estimate urban  $f_{NRB}$ , it has been assumed that woodfuels consumed in towns and cities are harvested and transported from the rural areas. As they are exploited commercially, urban fuelwood and charcoal tend to have higher impact than wood harvested for subsistence use by rural households. To account for this, the experts carried out a simple statistical analysis that considered a weighted average of the rural administrative units with higher  $f_{NRB}$ . This resulted in urban  $f_{NRB}$  values that are several percentage points higher than the national average. For example, it was estimated that Sierra Leone's national  $f_{NRB}$  is  $4\frac{10}{8}$ %  $\pm 15\%$ .  $f_{NRB}$  in its four main administrative units ranges from 36% to 50%, and the  $f_{NRB}$  in Freetown and other urban centers was calculated to be 42%  $\pm 15\%$ . The MP, while acknowledging the work undertaken by the experts, considers further analysis needs to be undertaken to assess the urban  $f_{NRB}$  values before it recommends the urban  $f_{NRB}$  values to the Board.
- The experts' determine also uncertainty levels for the f<sub>NRB</sub> estimates. 30 scenarios were run for that purpose by varying the values of Rmax defining the shape of the growth curves in the different ecological zones. These Rmax values were derived from IPCC 2019 information. It needs to be noted that the information provided by IPCC has high uncertainty (standard deviation similar to the average value) which results in high uncertainty for f<sub>NRB</sub> estimates. The panel is of the view that these uncertainty levels, due to the lack of detailed information about basic parameters like the growth rate of various forest types would be difficult to apply to conservatively adjust the f<sub>NRB</sub> central values calculated with the model.
- 45. With regard to uncertainty estimates in MoFuSS, the model uses Monte Carlo simulations (30 iterations per scenario) to assess uncertainty in its predictions, particularly for values like the fraction of non-renewable biomass (f<sub>NRB</sub>). Instead of reporting standard deviation (SD), which measures variability among individual simulation outputs, MoFuSS reports the standard error (SE)—a measure of the uncertainty in the mean estimate. This choice aligns with statistical best practices, especially for applications like carbon accounting, where confidence in the average prediction is more important than the variability of individual runs. By reporting SE, MoFuSS provides a clearer indication of the precision and reliability of its mean outputs, which are used for policy and baseline setting.
- 46. MoFuSS Uses Standard Error (SE) as it:
  - (a) Focuses on Precision: SE shows how precisely the mean is estimated—critical for policy and baseline decisions.
  - (b) Suited for Monte Carlo Methods: SE appropriately reflects uncertainty in the mean outcome, which is the goal of Monte Carlo simulations.

- (c) Statistical Best Practice: Reporting SE aligns with expert guidelines when the mean is the primary result of interest.
- (d) Avoids Misinterpretation: SD could misleadingly suggest problematic variability, while SE rightly emphasizes the reliability of the average prediction.

Figure 1. National f<sub>NRB</sub> values at the country level averaged for the period 2020-2030 (new figure below replacing the previous figure)

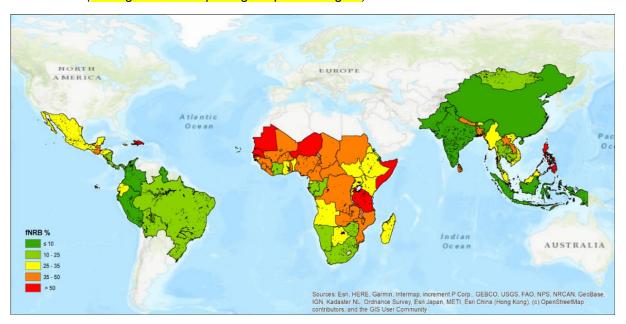

Figure 2. f<sub>NRB</sub> values at the first administrative level for the period 2020-2030 (new figure below replacing the previous figure)

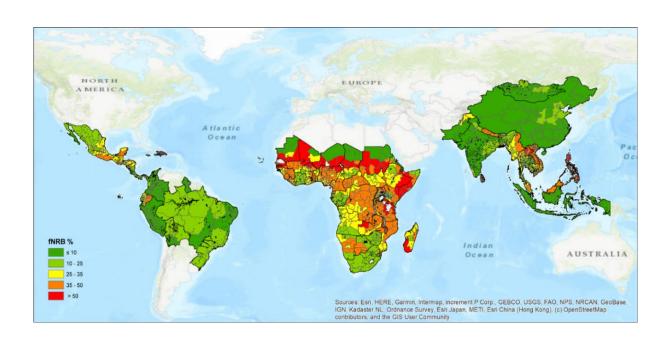

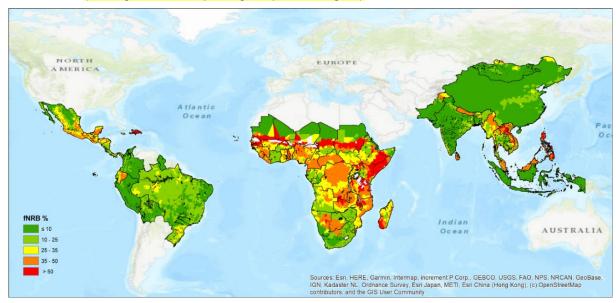

Figure 3. fNRB values at the second administrative level for the period 2020-2030 (new figure below replacing the previous figure)

By examining the maps above, it is clear that there is spatial variation across all world regions mostly in Africa. For example, Southern Africa has lower f<sub>NRB</sub> than the other subregions. There is also variation across countries within sub-regions, and within countries at sub-national levels. There are many factors that could drive this variation, including infrastructure and accessibility, population density, tree cover at the start of the simulation, and woodfuel demand trajectories predicted by WHO's database. All of the causes of spatial variation are not covered in this report. However, some differences are likely driven by a few key variables. For example, the lower f<sub>NRB</sub> outcomes in Southern African countries are very likely due to lower demand relative to supply than in other sub-regions. In the case of South Africa and Kenya, both countries have populations of over 50 million people, and both have substantial areas of arid or semi-arid land with little or no tree cover. The WHO estimates that in 2020, roughly 5 million people in South Africa used woodfuels as their primary cooking fuel. In contrast, in Kenya (less than half the size of South Africa), over 40 million people used woodfuels as their primary cooking fuel.

## 4. Impacts

48. National Isub-national and regional (continental) values of f<sub>NRB</sub> will ensure the reliability of calculating emission reductions, reduce transaction cost and facilitate the implementation of CDM project activities and PoAs in the household cookstove or water purification sector.

#### 5. Recommendations to the Board

- The MP recommends that the Board approve the default sub-national, regional (continental)—and national global values of f<sub>NRB</sub> for the countries respectively shown in Table 1 and 2 of Appendix 1, Table 2 and Table 3 of Appendix 2 and also included in the updated version of TOOL33- Default values for common parameters<sup>10</sup>.
- 50. The MP recommends the national values may to be used. if it can be justified that the project activity has an impact on fuelwood harvesting all over the host country. Where national/sub-national values are not listed in the aforementioned tables, regional

<sup>&</sup>lt;sup>10</sup> Refer to Annex 4 of MP 96 meeting report. (Refer to Annex 1 of MP 97 report).

(continental) values may be used. Further, stakeholders may submit new methodological approaches for the calculation of f<sub>NRB</sub> values that results in further advancements in terms of accuracy and conservativeness as per existing procedures for consideration by the Board. may use the relevant regional value in Table 1 of the Appendix 2.

- 51. The MP also recommends that for urban project activities where more than 20% of the fuelwood is imported, the relevant  $f_{NRB}$  should be calculated as the weighted average of the  $f_{NRB}$  values from the source areas.
- 52. The MP recommends the discontinuation of TOOL30 with effect from 1 Jan 2026.
- 53. The MP will has updated the relevant methodologies where the TOOL30 and/or fnrb values are referred to.
- 54. The MP is also of the view that the MoFuSS model could be used by the Project Participants to define the appropriate geographic area around the project site to develop a project specific f<sub>NRB</sub>. The MoFuSS model is open access and accessible to public.
- 55. The MP seeks further mandate to
  - (a) Undertake additional work on the calculation of f<sub>NRB</sub> using the marginal approach; the f<sub>NRB</sub> values estimated so far determines the share of the current fuelwood harvest taking place in elemental areas (pixels) where overharvesting can be observed. The marginal f<sub>NRB</sub> value reflects the fact that reduction of fuelwood harvest triggered by a project activity does not uniformly impact the harvesting activity in each elemental area uniformly and therefore results in a different f<sub>NRB</sub> for the reduced amount of fuelwood due to the implementation of the project activity. MoFuSS can be used to provide some information on this issue;
  - (b) Explore further the data on the calculation of urban f<sub>NRB</sub>-and the localisation of wood harvesting for charcoal production supplying the urban areas; and
  - (c) Assess the optimal geographical disaggregation for the estimation of f<sub>NRB</sub> values taking into account e.g. the uncertainty level of estimates at different geographical levels and fuelwood and charcoal flows between different sub-national jurisdictions or across national borders.
- The MP noted that the availability of data on demand for woodfuel and on the growth rates of forests is limited, which adds to the uncertainty of the f<sub>NRB</sub> values. The MP would like to request the Board to make a call to other agencies and entities to enhance their efforts to collect such data.

## 2. Subnational level (the first administrative level)

Tables 2 and 3 below provide preliminary results of the f<sub>NRB</sub> values at the subnational level for the Republic of Congo and Mauritania respectively, both of which show high variability.
